Durable rock fills are susceptible to saturation and severe erosion of fill material, with consequent downslope flooding or mudflows, during significant rainfall events, particularly during the final stages of construction. Lack of contemporaneous reclamation of durable rock fills has been a contributing factor to severe erosion and flooding. One of the most notable significant flooding events associated with durable rock fill construction occurred in Lyburn, West Virginia in 2002. While researching other failures following the event, WVDEP concluded that 49 excess spoil fill washouts had occurred in the 5 years preceding the Lyburn event (Pierce, 2004). To prevent or minimize offsite impacts, West Virginia Department of Environmental Protection (WVDEP) began requiring that durable rock fills be constructed in lifts of no more than 100 feet in thickness. Alternatively, fills may be constructed with an erosion protection zone, which is a free-draining durable rock bench extending downstream from the toe of the fill. It is intended to trap any fill material eroding, sliding, or flowing from an end-dumped fill during construction or final reclamation. Leaving fills with unreclaimed exposed surfaces increases the likelihood for mass soil movement and flooding.

The thick lifts and lack of mechanical compaction of spoil placed in durable rock fills results in greater void spaces and increased infiltration of both surface water and groundwater. These factors result in discharges containing elevated levels of total dissolved solids. Sections 3.5 and 4.2.1 of this FEIS discuss the effects of mining activities on water quality.

The final type of excess spoil fill is the disposal of excess spoil on pre-existing mine benches. Placement of excess spoil on these benches both assists in the reclamation of abandoned mine lands and reduces the number and size of excess spoil fills in areas that have not been previously impacted by mining. The federal requirements at 30 CFR 816.74 and 817.74 regarding placement of excess spoil on pre-existing benches are similar to the requirements for backfilling and grading, more so than the requirements that apply to construction of excess spoil fills on previously undisturbed terrain.

4.2.3.1.1.9 Trends in Excess Spoil Disposal

Since January 2000, at least 2,343 excess spoil fills have been authorized in Kentucky, Virginia, Tennessee, and West Virginia. The majority of these fills were authorized by Kentucky, which approved the construction of 1,488 valley fills through July 30, 2008. West Virginia authorized 511 excess spoil fills through the same time period. Virginia authorized 327 excess spoil fills through August 17, 2009, while Tennessee authorized 17 excess spoil fills through December 31, 2008. Between October 1, 2001 and June 30, 2005, five excess spoil fills were authorized in the Colorado Plateau and four excess spoil fills were authorized in Washington and Alaska.

However, not all excess spoil fills that are authorized are actually constructed. For example, in Virginia, 97 of the 327 excess spoil fills authorized between January 2000 and August 2009 were completed, 103 were under construction, 90 had not begun construction, and 37 were either unnecessary or not constructed as of August 2009 (U.S. GAO, 2009).

From 2002 to 2005, the number of fills that Kentucky approved each year declined from 262 to 92 (65 percent reduction) and the number of fills that West Virginia approved each year declined from 86 to 56 (35 percent reduction). In addition, the average fill footprint in Kentucky declined from 19 to 7 acres (63 percent reduction) (OSMRE, 2008).

4.2.3.1.1.10 Relationship between AOC and Excess Spoil

AOC restoration requirements do not apply to excess spoil fills because section 701(2) of SMCRA (30 U.S.C. § 1291(2)) defines “approximate original contour” as “that surface configuration achieved by backfilling and grading of the mined area.” The construction of excess spoil fills does not involve backfilling of the mined area; instead, it involves disposal of spoil that is not needed to restore the approximate original contour of the mined area (OSMRE, 2008).

The federal regulations at 30 CFR 701.5 define "excess spoil" as "spoil material disposed of in a location other than the mined-out area; provided that spoil material used to achieve the approximate original contour or to blend the mined-out area with the surrounding terrain in accordance with §§ 816.102(d) and 817.102(d) of this chapter in non-steep slope areas shall not be considered excess spoil." Thus, spoil used to achieve AOC is not considered excess spoil. Moreover, under the excess spoil minimization policies adopted by Central Appalachian states, spoil that can be returned to the mined-out area without either creating slope instability or a non-AOC surface topography does not qualify as excess spoil. The proviso in the definition means that spoil from box cuts or first cuts in non-steep slope areas would not be excess spoil when that spoil is used to blend the mined-out area into the surrounding terrain.

4.2.3.1.1.11 Coal Mine Waste

The federal regulations at 30 CFR 701.5 define "coal mine waste" as having two components: coal processing waste and underground development waste. Coal produced by either surface mining or underground mining methods may contain non-coal mineral matter (clay, shale, etc.). These impurities may make the coal unsuitable for immediate use by the consumer so the coal is processed to remove impurities or blended with higher quality coal before delivery to the shipping point. The impurities removed during processing are known as "coal processing waste." Underground mining methods also generate underground development waste; i.e., waste rock that must be removed from the underground workings to facilitate the mining process.

Coal mine waste may be disposed of permanently in refuse piles. Coal processing waste also may be stored in impounding structures, which must be dewatered and modified as necessary to meet the standards for refuse piles after they are no longer needed for coal processing purposes. Refuse piles are subject to regulations similar to those for excess spoil fills in terms of design, location, and construction. They are not subject to AOC restoration requirements because they are placed outside the mined area. Coal mine waste disposal regulations may be found at 30 CFR 780.25, 784.16, 784.19, 816.81 through 816.84, and 817.81 through 817.84.

Coal mine waste storage and disposal facilities (slurry impoundments and refuse piles) traditionally have been constructed for individual underground mines and associated coal preparation plants. Many currently active storage and disposal facilities have evolved to accept coal mine waste from other mines and preparation plants. In Central Appalachia, the slurry resulting from the coal preparation process typically is stored in a large impoundment formed by constructing an embankment across an existing hollow or valley. In areas with very flat topography, such as the Illinois Basin, the embankment completely encircles the impoundment. In either situation, the embankment typically is constructed in stages using coarse refuse that is also a waste product of the coal preparation process. In both cases, the fine coal refuse resulting from the coal preparation process is pumped as slurry into the impoundment, from which the water typically is decanted or pumped to be reused. When slurry pumping ceases, the embankment typically is breached so that the basin can no longer impound standing water. The structure then must be reclaimed as a refuse pile.

Few new slurry impoundments have been permitted in the last 15 years. In 2001, there were 713 freshwater and coal mine waste impoundments associated with coal processing facilities in the U.S. (Greb et al., 2006; OSMRE, 2008). Many existing impoundments provide decades of storage capacity and are expanded in stages,[30] which may have minimized the need for new facilities during this time.

Another method of handling fine coal refuse involves partially dewatering the slurry at the preparation plant. The resulting semi-solid material is then disposed of separately or mixed and placed with the coarse refuse material as combined refuse. Transporting and placing the material has been problematic because of the relatively high moisture content of the partially dewatered fine refuse. Recent research suggests that one option may be to transport the fine refuse as a paste (thickened tailings) that can be pumped to a disposal location (MSHA, 2009b).

Most coal mined by underground methods is processed in preparation plants to control ash and, where applicable, to reduce pyritic sulfur.[31] Increased market specifications for higher quality coal initially led to greater percentages of material being considered waste; approximately 20 to 50 percent of the mine production was rejected during processing according to some studies (Lucas, et al., 1979; OSMRE, 2008). More recently, preparation plants have improved, resulting in considerably higher Btu yields; i.e., fewer Btu's lost in the preparation process, and therefore less reject per ton of coal processed.

4.2.3.1.1.12 Underground Mining

Face-up areas of underground mines typically have impacts analogous to those of a similarly situated surface mine of the same size. However, underground mining does have one unique potential impact on topography in that longwall mining will—and other methods of underground mining may, depending on the competence of the overlying rock and the extent of pillars left as support—result in the collapse of overlying strata after the coal is removed, a process known as subsidence. Subsidence may reach the surface, depending upon the depth of the mine and the competence of rock strata between the underground workings and the surface. Subsidence that reaches the surface will alter the surface configuration and topography. Subsidence also can dewater streams in whole or in part. Subsidence mechanisms are more fully discussed in Section 3.1 of this FEIS.

Underground mining also can dewater streams or diminish flows by fracturing strata that support perched aquifers or by draining aquifers to facilitate mining.

Face-up areas and disturbed areas associated with support facilities are subject to the backfilling and grading requirements of 30 CFR 817.102 through 817.107, including the requirement to restore the land to its AOC. However, 30 CFR 817.102(l) provide an exception for settled and revegetated fills that result from the creation of the face-up of underground mines or from underground development waste. If such fills meet certain environmental, safety, stability, and postmining land use criteria, the regulation does not require that the operator use of the material in the fills to restore the AOC.

---

[30] In the Appalachian Basin region, existing slurry impoundments typically are expanded vertically by raising the coarse refuse embankment in stages, thus covering more of the upper reaches of the valley. In the Illinois Basin region, operators may raise the height of the encircling embankment, but, more typically, they expand horizontally with construction of an adjacent cell or cells in series with the existing impoundment.

[31] The Clean Air Act Amendments of 1990 required power plants to lower their emissions of sulfur dioxide, which, in some cases, resulted in modification of the coal preparation process to reduce its sulfur content.

4.2.3.1.2 Soils

Soils comprise the thin, weathered surface layer that overlies rock or other parent material. They are the medium in which most plant growth occurs, and their thickness, fertility, and structure are significant determinants of plant and ecosystem productivity. Soils are affected by underlying geologic material, climate, topography, biological factors, and time. Under 30 CFR 816.22(a), the operator must remove all topsoil, which 30 CFR 701.5 defines as consisting of the A and E soil horizons, before otherwise disturbing the land. If the topsoil is less than 6 inches in thickness, the operator must remove the top 6 inches of unconsolidated material. The topsoil must be either redistributed on a portion of the mine site upon which backfilling and grading has been completed or stockpiled until redistribution can occur. Under 30 CFR 816.22(d), the topsoil must be redistributed in a manner that achieves an approximately uniform, stable thickness when consistent with the postmining land use, contours, and surface-water drainage systems. Soil thickness may be varied to the extent that such variations would help meet specific revegetation goals identified in the permit.

If the soil is prime farmland historically used for cropland, 30 CFR 823.12(b) requires salvage and redistribution of not only all topsoil, but also enough material from the B and C soil horizons to reconstruct a soil with a depth of at least 48 inches, unless the premining soil contains a subsurface horizon at a lesser depth that inhibits or prevents root penetration. Paragraph (e) of 30 CFR 816.22 also allows the regulatory authority to require salvage and redistribution of the B and C soil horizons for non-prime farmland if those horizons are necessary to meet revegetation requirements.

Soils reconstructed after mining differ biologically, physically, and chemically from their premining counterparts. They are more uniform in texture, organic matter content, and thickness. Historically, soils on reclaimed mine sites are more compacted and contain higher amounts of rock fragments than unmined soils (Bussler, et al., 1984). However, specialized soil handling techniques can minimize compaction and reduce the adverse impacts of compaction on soil productivity and the hydrologic regime.

Prior to the implementation of SMCRA, coal mining activities often destroyed or degraded the topsoil. In addition, erosion of soil and mine spoil has caused serious sedimentation problems with resultant negative impacts to water quality and aquatic organisms. The legacy of these past practices can be seen today on pre-SMCRA abandoned coal mine sites. Mining operations removed or mishandled large amounts of soil at both surface and underground mining operations. Soils were lost or compacted during mining and construction of ancillary facilities such as buildings and roads. Operations were frequently conducted without regard to protection of the soil resource.

Subsequent to the enactment of SMCRA, topsoil handling improved, but the methods used to remove and redistribute topsoil sometimes resulted in excessive compaction, which reduces the pore space for air and water and impedes root growth, making revegetation with desirable species more difficult and the reclaimed site less productive. Long-term storage of soil can adversely alter texture and structure. In addition, mycorrhizae, soil organisms, and organic matter do not persist long in stockpiled topsoil.

The regulations implementing SMCRA are intended to minimize the impacts of mining on topsoil. In particular, 30 CFR 779.21, 780.18, 784.13, 816.22, and 817.22 require that the topsoil be removed as a separate layer from the area to be disturbed, and then segregated. If the topsoil is less than six inches thick, the topsoil and the unconsolidated materials immediately below the topsoil must be removed and the mixture treated as topsoil. In cases where the topsoil is of insufficient quantity or poor quality for sustaining vegetation, the operator may use selected overburden materials as a topsoil substitute or supplement. However, before doing so, the operator must demonstrate to the regulatory authority that the resulting soil medium will be equal to or more suitable for sustaining vegetation than the existing topsoil, and that the resulting soil medium is the best available in the permit area to support revegetation. The operator must recover these substitute or supplemental materials as a separate layer from the area to be disturbed and then segregate them.

The regulations require that the operator segregate and stockpile topsoil and topsoil substitutes and supplements after removal when it is impractical to redistribute those materials promptly on regraded areas. Stockpiled materials must be selectively placed on a stable site within the permit area and protected from pollutants, unnecessary compaction, and wind and water erosion that could interfere with revegetation. A quick-growing vegetative cover or other measures may be used for protection.

The operator must redistribute topsoil and topsoil substitutes and supplements in a manner that achieves an approximately uniform, stable thickness when consistent with the approved postmining land use, contours, and surface-water drainage systems. However, the thickness of the redistributed materials may vary to the extent necessary to meet the specific revegetation goals identified in the permit. In addition, redistribution must be done in a manner that prevents excess compaction of the materials and protects them from wind and water erosion before and after seeding and planting.

The regulations at 30 CFR 785.17 and Part 823 establish special requirements for prime farmland. The operator must salvage and redistribute the A, E, B, and C soil horizons to (1) an aggregate depth of at least 48 inches, (2) a lesser depth equal to the depth to a subsurface horizon in the natural soil that inhibits or prevents root penetration, or (3) a greater depth if determined necessary to restore the original soil productive capacity. The regulations also require use of soil reconstruction specifications developed by the U.S. Natural Resources Conservation Service (NRCS).

4.2.3.1.3 Geology

Coal mining permanently alters the geological structure of the mined area because of the removal of coal and, for surface mines, overburden. Factors that determine the level of geological disturbance are the elevation of the lowest coal seam mined, the depth of overburden above this seam, and the area mined. Surface mining completely alters the geologic structure above the lowest coal seam mined in that previously discrete strata of rock and soil, each stratum with its own distinctive characteristics, are converted to a more or less uniform fragmented mixture of rubble. Typically referred to as spoil, this rubble consists of mixtures of the parent rocks, with percentages of rock types varying at different locations across the site. Overburden analysis is also conducted to identify the presence of acid-forming rocks. These acid-forming/toxic materials are isolated in the backfill.

Underground mining has a lesser impact on geology because the strata overlying the coal seam remain discrete. However, subsidence may affect the elevation, continuity, and capability of individual strata to function as an aquifer.

4.2.3.2 Action Alternatives and Potential Effects on Topography, Soils, and Geology

Table 4.2-22 summarizes the effects of various elements of the Action Alternatives on topography, geology, and soil resources. The text below further characterizes potential effects, organizing the discussion according to each Action Alternative element.

Table 4.2-22. Action Alternative Elements and Potential Effects on Topography, Geology, and Soils in Coal Mining Regions

Action Alternative Element	Topography	Geology	Soils	Indirect Impact
Baseline Data Collection and Analysis				■
Monitoring During Mining and Reclamation				■
Definition of Material Damage to the Hydrologic Balance Outside the Permit Area				■
Evaluation Thresholds				■
Stream Definitions				■
Mining Through Streams	■	■	■	
Activities In or Near Streams Including Excess Spoil and Coal Refuse	■		■	■
AOC Exceptions	■			■
Surface Configuration	■		■	■
Revegetation, Soil Management, and Reforestation			■	
Fish and Wildlife Protection and Enhancement				■

4.2.3.2.1 Protection of the Hydrologic Balance

None of the alternatives under consideration for the Protection of the Hydrologic Balance functional group would have any direct impacts on topography, geology, or soils. However, they could have an indirect effect on whether and where mining occurs, which in turn would determine whether and where mining-related impacts to topography, geology, and soils would occur. For example, after reviewing baseline data, analyzing monitoring results, or preparing the cumulative hydrologic impact assessment, the regulatory authority may decide either that the proposed operation cannot be approved or that the existing operation needs to modified to prevent material damage to the hydrologic balance outside the permit area.

4.2.3.2.2 Activities In or Near Streams

4.2.3.2.2.1 Stream Definitions

All of the Action Alternatives include definitions of perennial, intermittent, and ephemeral streams; these definitions formally delineate the key natural resource addressed by the proposed action. Current regulations classify all watersheds one square mile or larger in size as intermittent streams; some of the Action Alternatives would delete this provision. To the extent that this change would result in some streams (mostly in the arid and semiarid regions of the West) now protected as intermittent streams being reclassified as ephemeral streams, which lack the protections afforded to perennial and intermittent streams, there could be a direct adverse effect on topography and an indirect adverse effect on geology and soils.

4.2.3.2.2.2 Mining Through Streams

The existing regulations (No Action Alternative) allow mining through intermittent and perennial streams when the regulatory authority makes a finding that diversion of the stream will not adversely affect water quantity, water quality, and related environmental resources of the stream (see 30 CFR 816.43(b) and 817.43(b)). The No Action Alternative requires that a permanent stream-channel diversion or a restored stream channel be designed and constructed so as to approximate the premining characteristics of the original stream channel, including streamside vegetation, but it does not require restoration of the stream's biological condition or ecological function.

Under each Action Alternative (excluding Alternative 9), specific standards would guide stream restoration, such as the requirement to restore natural hydrologic form and ecological function for intermittent and perennial streams and restoration of natural hydrologic form for ephemeral streams. Alternatives 2 and 7 would explicitly prohibit mining through or within 100 feet of perennial streams. Alternatives 4, 5, 6, and 8 would require that applicants demonstrate that complete restoration of the hydrologic form and ecological function of intermittent and perennial streams can be accomplished. The requirement to restore form and function should minimize alterations in stream configuration and hydrological characteristics under these alternatives. The requirement to avoid effects on intermittent and perennial streams, or to apply a higher reclamation standard to some or all types of streams, would minimize the effect of mining through streams and any resultant impacts on topography and soils. Perennial and intermittent streams would be less likely to be mined through and, if they are mined through, the stream and its resources must be restored or replaced in most cases.

4.2.3.2.2.3 Activities In or Near Streams, Including Placement of Excess Spoil and Coal Refuse

The existing regulations at 30 CFR 816.57 and 817.57 (the No Action Alternative) prohibit disturbance of the land surface by mining activities within 100 feet of an intermittent or perennial stream unless the regulatory authority specifically authorizes activities closer to or through the stream. That authorization requires a finding that the mining activities will not cause or contribute to the violation of applicable state or federal water quality standards and will not adversely affect the water quantity or quality or other environmental resources of the stream. See 30 CFR 816.57(a)(1) and 817.57(a)(1). Historically, some regulatory authorities have applied this regulation in a manner that allows construction of excess spoil fills and coal mine waste disposal facilities in streams within the permit area, as long as the findings can be made with respect to the remaining portion of the stream below the toe of the fill or facility.

The Action Alternatives would increase the stringency of the requirements governing mining activities near streams as well as the placement of excess spoil and coal refuse at these locations. All Action Alternatives would require minimization of excess spoil creation. Likewise, all would require that the permit applicant identify and analyze a reasonable range of alternatives and select the alternative that results in the least adverse overall impact on fish, wildlife, and related environmental values.

Alternative 2 would prohibit all mining activity in or within 100 feet of a perennial stream; it also would prohibit placement of excess spoil in intermittent streams. Alternative 3 would prohibit placement of excess spoil or coal mine waste in a perennial stream.

Alternatives 4, 5, 6, 7, and 8 (Preferred) would allow construction of excess spoil fills and coal mine waste structures in or near perennial and intermittent streams, but they would place new restrictions on excess spoil fill construction techniques. These restrictions include a ban on fills constructed by end-dumping (durable rock fills); a ban on flat-topped fills (instead, the surface configuration of the top of the fill must be graded to resemble the surrounding topography); a requirement for construction of aquitards within the fill; a requirement for offsets of any long-term adverse impacts on fish and wildlife; and increased monitoring during fill construction. Alternative 9 would allow construction of excess spoil fills and coal mine waste structures in or within 100 feet of perennial and intermittent streams, but it would not place any significant new restrictions on excess spoil construction techniques.

To the extent that the Action Alternatives reduce mining in or near streams and reduce the footprint of excess spoil fills and coal mine waste structures, there would be fewer or less extensive alterations to the topography, geology, and soils of those areas. Likewise, requirements that the top decks of excess spoil fills be graded to resemble surrounding landforms would reduce adverse impacts on topography, at least in terms of visual impact.

4.2.3.2.2.4 Approximate Original Contour

4.2.3.2.2.5 AOC Exceptions

As discussed in Section 4.2.3.1, SMCRA and the existing regulations (the No Action Alternative) provide several exceptions to the requirement to restore mined land to AOC. Those exceptions include operations with thin or thick overburden, certain remining operations, mountaintop removal mining operations, and steep-slope mining operations. The latter two exceptions apply only when the mountaintop removal mining operation or the AOC variance for a steep-slope mining operation will facilitate one or more specified postmining land uses and certain other requirements are met. These two exceptions apply only to operations consisting primarily of steep slopes (slopes in excess of 20 degrees), a situation that occurs almost exclusively in Central Appalachia.

Under the No Action Alternative, the most visible impact of AOC exceptions on topography would be the continued limited creation of flat or gently rolling terrain in areas that previously contained primarily steep slopes. Alternative 2 would prohibit all AOC exceptions and would likely require amendment of SMCRA. Alternatives 3, 4, 5, and 8 (Preferred) likely would result in the approval of fewer operations with AOC exceptions. Therefore, Alternatives 2, 3, 4, 5, and 8 (Preferred) should result in fewer permanent effects on topography than would be expected under the No Action Alternative. Alternatives 6, 7, and 9 are similar to the No Action Alternative in terms of AOC exceptions and, thus, would have similar impacts.

4.2.3.2.2.6 Surface Configuration

As discussed in Section 4.2.3.1, SMCRA requires that the permittee backfill and grade the mined area to its AOC, which means a surface configuration that closely resembles the premining surface configuration and that blends into and complements the drainage pattern of the surrounding terrain. The existing regulations (the No Action Alternative) contain similar provisions. Alternatives 6, 8 (Preferred), and 9 would not alter the existing regulations with respect to surface configuration requirements.

Alternatives 2, 3, and 4 would require that almost all surface mining operations use digital terrain analysis techniques to determine whether AOC restoration requirements have been met. Alternatives 5 and 7 would require use of digital terrain analysis techniques for a smaller subset of operations; e.g., operations that dispose of excess spoil or coal mine waste.

Alternatives 2, 3, and 4 would require use of landforming principles as part of backfilling and grading to prevent the creation of uniform slopes vulnerable to erosion and to promote restoration of topographical features that will re-create microclimates and ecological niches present prior to mining. However, Alternative 3 would not apply those principles to excess spoil fills.

Alternatives 2 and 4 would require that the thickness of backfilled material at any point in the backfilled area not differ from the combined premining thickness of the coal seam and overburden strata at that point by more than ± 20 percent.

Alternatives 2, 3, and 4 would have the greatest impact on topography because they are most likely to ensure that the final surface configuration and landscape features more closely match the premining configuration and landscape features. The greatest impact would occur in regions with highly variable premining topography, such as mountainous terrain. Alternatives 5 and 7 would have a lesser impact on topography than Alternatives 2, 3, and 4, but a greater impact than the No Action Alternative. Alternatives 6, 8, and 9 would not differ in impact from the No Action Alternative.

4.2.3.2.3 Postmining Land Use and Enhancement

4.2.3.2.3.1 Revegetation, Soil Management, and Reforestation

The existing regulations (the No Action Alternative) at 30 CFR 816.111 through 816.116 and 817.111 through 817.116 require use of native species in revegetation, although introduced species are permitted under certain conditions. As described in Section 4.2.3.1 of this FEIS, salvage, storage, and redistribution of topsoil (the A and E soil horizons) is required for all operations, with the proviso that operations on prime farmland historically used for cropland typically must salvage, store, and redistribute the B and C soil horizons to the extent needed to provide a minimum of 48 inches of soil on the reclaimed area. Selected overburden materials may be used in place of the topsoil and subsoil if they meet specified criteria and are approved by the regulatory authority.

Under conditions of natural succession, establishment of a forest on bare soil would take 15 to 20 years (Groninger et al., 2007), or longer. The initial loss of forest habitat because of mining activities would be expected to have a negative impact on soils in these forested areas (Belnap and Eldridge, 2001).

Alternatives 2, 3, 4, 5, 7, and 8 (Preferred) require—

- Revegetation of reclaimed lands using only native species unless those species are incompatible with an approved postmining land use that is implemented during the revegetation responsibility period.

- Salvage and redistribution of topsoil, subsoil, and other suitable materials (not just topsoil as in the No Action Alternative) necessary to create the root zone needed to support revegetation (especially trees) and restore premining capability.
- Overburden materials used as a topsoil substitute or supplement must result in a growing medium that is more suitable for vegetation than the original topsoil or the topsoil alone.
- Salvage of organic matter (tree tops, root balls, duff, and other native vegetative debris). These materials must be mixed with the topsoil, redistributed over the re-soiled area, or used for fish and wildlife enhancement purposes.
- Reforestation of previously forested areas or areas that would revert to forest under natural succession unless reforestation is inconsistent with an approved postmining land use that is implemented before the end of the revegetation responsibility period.
- Revegetation success standards must be developed to demonstrate that the permittee has restored the land's capability to support all uses it was capable of supporting before any mining, not just the approved postmining land use as under the No Action Alternative.

These alternatives would enhance fish, wildlife, and related environmental values and ensure that the reclaimed site can support the uses it was capable of supporting before any mining, including the vegetation that it would support in the absence of human influence. These alternatives would restore previously forested areas to a native forest ecosystem as quickly as possible, except where doing so would conflict with the approved postmining land use and that use is implemented before the end of the revegetation responsibility period. Alternatives 2, 3, 4, 5, 7, and 8 (Preferred) would beneficially impact soil quality and productive capability both directly in the form of improved soil reconstruction requirements and indirectly in the form of improved revegetation requirements. Alternatives 6 and 9 would have the same impacts as the No Action Alternative.

4.2.3.2.4 Fish and Wildlife Protection and Enhancement

Section 515(b)(24) and 516(b)(11) of SMCRA (30 U.S.C. §§ 1265(b)(24) and 1266(b)(11)) require that surface coal mining and reclamation operations minimize disturbances and adverse impacts of the operation on fish, wildlife, and related environmental values to the extent possible using the best technology currently available; they also require enhancement of those resources where practicable. The existing regulations (the No Action Alternative) at 30 CFR 773.15(j), 816.97(b), and 817.97(b) prohibit the approval of a permit or the conduct of mining activity likely to jeopardize endangered or threatened species or result in the destruction or adverse modification of designated critical habitat. The existing regulations at 30 CFR 780.16 and 784.21 require that each permit application include fish and wildlife resource information and a fish and wildlife protection plan. The existing regulations at 30 CFR 816.97(a) and (e) and 817.97(a) and (e) contain corresponding performance standards requiring enhancement of fish, wildlife, and related environmental values where practicable; they also require implementation of protective measures during mining in all cases. The remainder of existing 30 CFR 816.97 and 817.97 require additional protective measures for fish and wildlife, including avoidance of disturbances to, restoration, or replacement of wetlands, riparian vegetation, and other habitats of unusually high value for fish and wildlife.

The Action Alternatives would improve implementation of sections 515(b)(24) and 516(b)(11) of SMCRA by further protecting fish, wildlife, and related environmental resources through measures such as mandatory enhancement measures to offset any long-term environmental impacts as well as a requirement for establishment or restoration of a minimum 100-foot (Alternatives 2, 5, 6, 7, and 8) or 300-foot (Alternatives 3 and 4) streamside vegetative corridor comprised of native species along intermittent, perennial, and (sometimes) ephemeral streams. None of the alternatives, including the No Action Alternative, would have a direct impact on topography, geology, or soils, although all alternatives may have an indirect impact to the extent that they might encourage operators to avoid mining areas of high habitat value.

4.2.3.3 Assessment of Quantified Impacts to Topography, Geology, and Soils

The analysis considers three indicators for characterizing the quantified impacts of the alternatives on topography, geology, and soils:

- First, impacts are directly dependent on the amount of coal mined. Hence, changes in coal production forecasted for the alternatives provide a rough indicator of potential changes in adverse impacts to topography, geology, and soils.
- Second, some of the requirements under the alternatives affect the intensity of land disturbance, i.e., the number of acres disturbed per ton of coal mined.
- Third, an analysis of likely premining and postmining slope ranges provides a measure of how the alternatives may affect topographical changes associated with mining.

Each of these indicators is discussed below.

4.2.3.3.1 Coal Production Impacts

Mining itself constitutes a disturbance to topography, geology, and soils. Thus, the Action Alternatives will impact topography, geology, and soils to the extent they influence the quantity of coal produced in a particular region. Table 4.2-23 reviews the average annual change in coal production projected for each Action Alternative relative to the No Action Alternative, averaged over the period from 2020 to 2040. Key observations include the following:

- To varying extents, all Action Alternatives (except Alternative 9) would decrease coal production.
- Under all Action Alternatives, coal production would decrease the most in the Appalachian Basin, Illinois Basin, and Northern Rocky Mountains and Great Plains regions.
- In other regions, the Action Alternatives would have negligible effects on future coal production.
- Alternative 2 would result in the largest reduction in coal production. Hence, it likely would have the least adverse impact on topography, geology, and soils of all the alternatives.
- Underground mining typically causes less disturbance to topography, geology, and soils than surface mining.

Table 4.2-23. Regional Forecasted Change in Average Annual Coal Production under the Actions Alternatives Compared to the No Action Alternative, 2020 to 2040 (Millions of Tons)

Alternative	Mine Type	Appalachia	Colorado Plateau	Gulf Coast	Illinois Basin	Northern Rocky Mountains	Northwest	Western Interior	Total
Alternative 2	Surface	(0.3)	0	(0.0)	(0.1)	(0.1)	0	0	(0.5)
	Underground	(0.5)	0	-	(0.4)	0	-	0.0	(0.9)
	Net Change	(0.8)	0	(0.0)	(0.4)	(0.1)	0	0	(1.3)
Alternative 3	Surface	(0.2)	0	(0.0)	0	(0.0)	0	0	(0.2)
	Underground	(0.3)	0	-	(0.3)	0	-	0	(0.6)
	Net Change	(0.5)	0	(0.0)	(0.3)	0.0	0	0	(0.8)
Alternative 4	Surface	(0.1)	0	(0.0)	(0.1)	0.0	0	0	(0.2)
	Underground	(0.3)	0	-	(0.3)	0	-	0	(0.6)
	Net Change	(0.4)	0	(0.0)	(0.3)	0.0	0	0	(0.7)
Alternative 5	Surface	(0.1)	0	(0.0)	0	(0.0)	0	0	(0.1)
	Underground	(0.2)	0	-	0	0	-	0	(0.2)
	Net Change	(0.4)	0	(0.0)	0	(0.0)	0	0	(0.4)
Alternative 6	Surface	(0.1)	0	0.0	0	(0.0)	0	0	(0.1)
	Underground	(0.1)	0	-	(0.3)	0	-	0	(0.4)
	Net Change	(0.2)	0	0.0	(0.3)	(0.0)	0	0	(0.5)
Alternative 7	Surface	(0.1)	0	0.0	(0.1)	0.0	0	0	(0.2)
	Underground	(0.3)	0	-	(0.4)	0	-	0	(0.7)
	Net Change	(0.4)	0	0.0	(0.4)	0.0	0	0	(0.8)
Alternative 8	Surface	(0.1)	0	0	0	(0.1)	0	0	(0.2)
	Underground	(0.2)	0	-	(0.3)	0	-	0	(0.5)
	Net Change	(0.3)	0	0	(0.3)	(0.1)	0	0	(0.7)
Alternative 9	Surface	0	0	0	0	0	0	0	0
	Underground	0	0	-	0	0	-	0	0
	Net Change	0	0	0	0	0	0	0	0

Note: Parentheses indicate a negative change in forecasted coal production. Totals may not sum due to rounding. Please refer to Section 4.1 for a more detailed discussion of these forecasted changes.

Section 4.1 of this EIS provides a more detailed discussion of the forecasted change in coal production under each alternative.

4.2.3.3.2 Disturbed Area

Another key component of this analysis concerns changes in the size of the area disturbed by coal mining. The analysis quantifies these changes based on estimated rates of acreage disturbed per million tons of coal mined, as determined in the model mines analysis (see Section 4.1). Disturbed areas include all areas from which mining-related activities remove vegetation, topsoil, or overburden, and all areas upon which the operation places spoil, coal mine waste, or other mining-related materials.

The analysis indicates that impacts would be concentrated in Central Appalachia and would primarily affect surface mines. The Action Alternatives would not result in changes in disturbed area in any other region. Therefore, this section discusses only the impacts on Central Appalachia.

Table 4.2-24 shows changes in the acreage disturbed per million tons of coal mined for the Central Appalachian region surface mines. The table presents both the absolute acreage as well as the change in disturbed acreage relative to the No Action Alternative. The general finding is that under certain Action

Alternatives, less land is disturbed per million tons of coal mined by surface methods in Central Appalachia. The decrease in the disturbance rate likely would reduce adverse impacts on topography, geology, and soils. Specific observations include the following:

- For Central Appalachian surface mines (excluding contour mines), Alternatives 3 through 9 disturb the same amount of land per million tons of coal mined as under the No Action Alternative. Alternative 2, however, has a slightly lower disturbance rate.
- For Central Appalachian surface contour mines, Alternatives 3 and 9 disturb land at the same rate as the No Action Alternative. Alternative 2 significantly reduces land disturbance rates for surface contour mines. The other Action Alternatives (4 through 8) disturb slightly less land per million tons of coal mined as under the No Action Alternative.

Table 4.2-24. Disturbed Area, Minable Coal, and Disturbed Area per Million Tons of Coal Mined for Central Appalachian Surface Model Mines: Potential Total Acreage Compared to the No Action Alternative

	Disturbed area per mine (acres)	Volume of mineable coal per mine (million tons)	Disturbed area per million tons mined (acres/million tons)
Central Appalachian Surface Area Mine			
No Action, Alternatives 3 through 9	**1,260**	**37**	**34**
Alternative 2	**1,116**	**37**	**31**
Central Appalachian Surface Contour Mine			
No Action, Alternatives 3 and 9	**458**	**5**	**92**
Alternative 2	**371**	**5**	**74**
Alternatives 4 through 8	**448**	**5**	**90**
Note: Totals may not sum due to rounding.			

Finally, the shift to underground mining under Alternative 2 in the Appalachian Basin would further decrease the negative effects on topography, soils, and, to a lesser extent, geology, given that underground mines disturb significantly less area per million tons of coal produced than surface mines.

4.2.3.3.3 Slope Changes and Topographical Impacts

A comparison of premining and postmining slopes using the model mines analysis indicates that all alternatives would result in no more than a one percent change in slope, with the exception of the Central Appalachian and Northern Appalachian regions. The change in slope is used as an indicator of the severity of the change in topography.[32] The objective is to determine whether the Action Alternatives reduce the topographical moderation (i.e., the change from steeper slopes before mining to more moderate slopes after mining) often associated with mining.

[32] This is an oversimplification because topography represents the three-dimensional arrangement of physical attributes (shape, elevation, and volume), and typically includes an analysis of aspect (direction of slope) of a land's surface and elevation. While important, aspect and elevation are more difficult to characterize across a large area and many model mines. Therefore, they were not included in this analysis.

Surface mines in the Northern Appalachian region exhibited no clear trends with respect to topographical moderation. However, Tables 4.2-25 and 4.2-26 and Figures 4.2-7 and 4.2-8 indicate that Alternatives 2, 4, and 8 would result in measurable differences between premining and postmining slopes for surface mines in the Central Appalachian region compared to the differences between premining and postmining slopes that would exist under the No Action Alternative. Specifically, Alternatives 2, 4, and 8 (Preferred) would result in a lower proportion of flatter postmining slopes and a higher proportion of steeper postmining slopes relative to the other Action Alternatives.

Table 4.2-25. Analysis of Slope Change for Central Appalachian Surface Area Mines[4]

Alternative	Slope Range	Acreage[2]	Percentage[3]	Difference from No Action Alt. (acres)
No Action Alternative[1]	<5%	202	14.3%	0
	5%-10%	16	1.2%	0
	10%-15%	26	1.8%	0
	15%-35%	136	9.6%	0
	35%-45%	156	11.1%	0
	45%-55%	754	53.5%	0
	>55%	119	8.4%	0
Alternative 2	<5%	154	10.9%	-48
	5%-10%	20	1.4%	3
	10%-15%	24	1.7%	-2
	15%-35%	148	10.5%	13
	35%-45%	119	8.4%	-37
	45%-55%	737	52.3%	-17
	>55%	207	14.7%	88
Alternatives 4 and 8	<5%	129	9.2%	-73
	5%-10%	19	1.4%	3
	10%-15%	29	2.1%	3
	15%-35%	268	19.0%	132
	35%-45%	137	9.7%	-19
	45%-55%	708	50.3%	-46
	>55%	118	8.3%	-1

Notes:
[1] Alternatives 3, 5, 6, 7, and 9 would have slope changes comparable to those that would occur under the No Action Alternative.
[2] Mine area acres within designated slope range category.
[3] Percent of total mine area within designated slope range category.
[4] Based on model mine analysis.

4.2.3.4 Summary of Effects

Table 4.2-27 summarizes the impacts to topography, geology, and soils under each of the Action Alternatives as compared to the No Action Alternative.

The extent to which the Action Alternatives would impact topography, geology, and soils is in part dependent upon the extent to which the Action Alternatives would affect coal production because the process of coal mining necessarily disturbs the topography, geology, and soils of the mine site. Because the Action Alternatives generally result in minor reductions in the volume of coal anticipated to be mined, and also attempt to reduce erosion and runoff, as well as other adverse impacts on soils, impacts are generally anticipated to be beneficial, although the EIS does not attempt to quantify these benefits. Impacts are generally likely to extend beyond the period of active mining (long-term). Specifically, determinations were made using the following analytical categories:

- Negligible: Minimal measurable impacts (adverse or beneficial) are expected; or short term effects to a small geographic area, community or economy.
- Minor Beneficial: Benefits to soil or geologic features could be detectable, but would be small and localized. Reduced erosion and/or subsidence could occur in localized areas.
- Moderate Beneficial: Benefits to geologic features or soils could be readily apparent and result in improvements to the soil character or local geologic characteristics in local and adjacent areas. Erosion and subsidence impacts could be reduced in local and adjacent areas.
- Major Beneficial: Benefits to geologic features or soils could be readily apparent and result in improvements over a widespread area. Erosion and subsidence impacts could be reduced over a widespread area. Improvements to geologic features or soils could be permanent.

In general, the effects of the Action Alternatives on these resources are expected to be Negligible or Beneficial across all coal regions. Coal mining is both geographically widespread and of major economic importance in the Appalachian Basin region, so each Alternative that would apply to all mining operations is rated as having an impact of at least medium geographic scope for that region.

4.2.3.4.1 Alternative 1 (No Action Alternative)

Under the No Action Alternative, no further regulations or corrective measures in addition to those already in place would be implemented. Therefore, ongoing trends in geology, soils, and topography would continue. The annual quantity of coal demanded and associated production is anticipated to be approximately 10 percent lower in 2040 than in 2020, even without implementation of the Alternatives (i.e., under the No Action Alternative). This reduction in production would reduce adverse impacts of ongoing geology, soils, and topography under the No Action Alternative.

Population growth is a primary driver of disturbances to topography, geology, and soils associated with land clearing and development. As stated above, in the period from 2000 to 2010, the coal regions seeing the greatest growth tended to be those in western states. The Northern Rocky Mountains and Great Plains region showed a 21 percent growth in population during this period, making it the fastest growing coal region. Other rapidly growing regions include the Colorado Plateau and the Gulf Coast regions. In terms of 2010 population, the most populous coal regions are the Appalachian Basin and the Illinois Basin. These population growth pressures are likely to increase disturbances to topography, geology, and soils under the No Action Alternative.

Trends in forestry under the No Action Alternative would also affect topography, geology, and soils, particularly as forest cover influences runoff. Approximately 60 percent of land in the Appalachian Basin is deciduous forest and several large National Forests exist in the region. While trends vary by sub-region, some portions of the Appalachian Basin have seen increased timber harvests in recent years. For instance, West Virginia production of industrial roundwood roughly doubled from 1979 to 2007, totaling nearly 190 million cubic feet (Piva and Cook, 2011). In the Gulf Coast region, Mississippi and Louisiana have extensive commercial forestry operations. Forest products were the highest value crop harvested in Louisiana in 2010, worth over three billion dollars (Louisiana Forestry Association, 2011). In Mississippi, the timber harvest was valued at $1.1 billion in 2013 (Mississippi State University, 2014). In addition, the Texas timber industry is concentrated almost exclusively in the northeast portion of the state (near Louisiana), meaning that it is almost fully contained in the Gulf Coast coal region (Texas Almanac, 2014). The delivered value of Texas timber was roughly $500 million in 2011. State forestry programs may promote best management practices (BMPs) that are intended to protect water resources, among other resources. For example, Tennessee's BMP guide recommends practices such as establishment of streamside buffer zones, soil stabilization through reforestation, and use of sediment control structures (Tennessee Department of Agriculture, 2003). In conjunction with the proposed action, these BMPs could reduce forestry impacts such as sedimentation and streamside vegetation removal.

Trends in agriculture also influence topography, geology, and soils within the study area. Relative to the other coal-producing regions, the Illinois Basin has the greatest amount of cultivated cropland. Cropland accounts for over 48 percent of the land use in this coal region. Illinois had approximately 22 million acres of harvested cropland in 2012, roughly unchanged from 2007. The total value of all agricultural products sold in 2012 was about $17.2 billion, up significantly from 2007 when sales totaled $13.3 billion (USDA, 2014). Livestock grazing is common in several coal-producing regions. In the Western Interior region, pasture and grazing operations account for over 38 percent of the land use in Kansas and Oklahoma. Likewise, the Gulf Coast region is over 26 percent pastureland.

In concert with the above, efforts to decrease runoff of topsoil, actions such as erosion control programs, watershed protection programs, and habitat conservation programs seek to reduce adverse impacts of land development activities under the No Action Alternative.

4.2.3.4.2 Alternative 2

4.2.3.4.2.1 Topography

Alternative 2 would eliminate the AOC exception for mountaintop removal mining operations. It also would eliminate all steep-slope AOC variances, prohibit placement of excess spoil or coal mine waste in perennial streams, and prohibit placement of excess spoil in intermittent streams.

Alternative 2 would require use of digital terrain models to document premining and postmining surface configurations of the mined area, with the exception of remining operations and non-contiguous permits no more than 40 acres in size. The final thickness of backfilled and graded spoil placed in the mined-out area could not vary from the combined premining thickness of overburden and the coal seam by more than ±20 percent at any point on the backfilled area. Landforming principles would apply to both backfilled and graded areas and to excess spoil fills. These requirements should reduce mining-related topographic changes. Alternative 2 also would establish more stringent approval criteria for mining through intermittent streams and would require restoration of the ecological function of intermittent streams that are mined through.

4.2.3.4.2.2 Geology

Alternative 2 would prohibit mining within 100 feet of a perennial stream, which should prevent impacts to the geology of those areas. The benefits of reduced coal production would be largest under this alternative, but would remain small compared to the overall level of coal production anticipated.

4.2.3.4.2.3 Soils

Alternative 2 would require salvage and redistribution of all topsoil (the A and E horizons) and sufficient quantities of subsoil (B and C horizons) or other suitable materials to provide optimal rooting depths to restore premining land use capability or to comply with revegetation requirements. Alternative 2 also would require salvage of all native vegetation and other organic materials, including root balls, which must be incorporated into the topsoil, redistributed on the surface of topsoiled areas, or used for stream restoration or fish and wildlife enhancement purposes.

Alternative 2 would allow use of selected overburden materials as substitutes for (or supplements to) topsoil or subsoil, but only if the operator demonstrates that: (1) the quality of the existing topsoil and subsoil is inferior to that of other overburden materials; or (2) the quantity of the existing topsoil and subsoil is insufficient to provide the optimal rooting depth or meet other plant growth requirements. In the latter case, all existing topsoil and favorable subsoil must be salvaged and redistributed. The operator also must demonstrate that the resulting soil medium would be more suitable than the existing topsoil and subsoil to sustain vegetation, and that the selected overburden materials are the best available within the permit area for that purpose. The operator would be required to redistribute soils in a manner that limits compaction and provides optimal rooting depth to support the approved plan for revegetation and reforestation.

These requirements should reduce some of the adverse soil effects, particularly those related to compaction and the lack of a suitable root zone and growing medium for reforestation that can result from mining under the No Action Alternative.

Impacts on topography, geology, and soils would vary by region. Each region is discussed in the following sections.

Table 4.2-27. Summary of Impacts of the Action Alternatives on Topography, Geology and Soil Resources As Compared to the No Action Alternative

Alternative	Metric	Appalachian Basin	Colorado Plateau	Gulf Coast	Illinois Basin	Northern Rocky Mountains and Great Plains	Northwest	Western Interior	National
Alternative 2	Classification	Moderate Beneficial	Minor Beneficial	Minor Beneficial	Minor Beneficial	Minor Beneficial	Negligible	Negligible	Minor Beneficial
	Rationale	LT, MS	LT, SS	LT, SS	LT, SS	LT, SS	MMI	MMI	
Alternative 3	Classification	Minor Beneficial	Minor Beneficial	Minor Beneficial	Minor Beneficial	Minor Beneficial	Negligible	Negligible	Minor Beneficial
	Rationale	LT, MS	LT, SS	LT, SS	LT, SS	LT, SS	MMI	MMI	
Alternative 4	Classification	Moderate Beneficial	Minor Beneficial	Minor Beneficial	Minor Beneficial	Minor Beneficial	Negligible	Negligible	Minor Beneficial
	Rationale	LT, MS	LT, SS	LT, SS	LT, SS	LT, SS	MMI	MMI	
Alternative 5	Classification	Moderate Beneficial	Negligible	Negligible	Negligible	Negligible	Negligible	Negligible	Minor Beneficial
	Rationale	LT, MS	MMI	MMI	MMI	MMI	MMI	MMI	
Alternative 6	Classification	Negligible	Negligible	Negligible	Negligible	Negligible	Negligible	Negligible	Negligible
	Rationale	MMI	MMI	MMI	MMI	MMI	MMI	MMI	
Alternative 7	Classification	Moderate Beneficial	Negligible	Negligible	Negligible	Negligible	Negligible	Negligible	Minor Beneficial
	Rationale	LT, MS	MMI	MMI	MMI	MMI	MMI	MMI	
Alternative 8 (Preferred)	Classification	Moderate Beneficial	Minor Beneficial	Minor Beneficial	Minor Beneficial	Minor Beneficial	Negligible	Negligible	Minor Beneficial
	Rationale	LT, MS	LT, SS	LT, SS	LT, SS	LT, SS	MMI	MMI	
Alternative 9	Classification	Negligible	Negligible	Negligible	Negligible	Negligible	Negligible	Negligible	Negligible
	Rationale	MMI	MMI	MMI	MMI	MMI	MMI	MMI	

Notes:
LT = Long-term impact; LS = Large scope impact; MS = Medium scope impact; SS = Small scope impact; MMI = Minimal measurable impact.
For a discussion of the impacts of the No Action Alternative (Alternative 1), see Section 4.2.3.1 above.

4.2.3.4.2.4 Appalachian Basin Region

Alternative 2 would cause a decrease in total coal production for this region, which should decrease the total area disturbed by mining each year. In addition, the area disturbed per million tons of coal mined would decrease. With respect to topography, this alternative is the only alternative that would prohibit mountaintop removal mining operations and steep-slope AOC variances. It also would require use of landforming principles to design and construct the postmining surface configuration and the final thickness of backfilled and graded spoil placed in the mined-out area could not vary from the combined premining thickness of overburden and the coal seam by more than ±20 percent at any point on the backfilled area. The slope analysis indicates a decrease in topographic moderation, which results in a reclaimed surface topography that more closely resembles the premining surface configuration. This alternative would require that postmining soils be reconstructed with a root zone adequate to restore premining land use capability and fully support reforestation. Therefore, Alternative 2 would have long-term positive impacts of a medium geographic scope that would have a Moderate Beneficial effect on the topography, geology, and soils of this region.

4.2.3.4.2.5 Colorado Plateau and Gulf Coast Regions

Alternative 2 would have qualitative benefits to topography, geology, and soils in the Colorado Plateau and Gulf Coast regions, but substantially fewer topographical benefits than in the Appalachian Basin region because the former regions have a much flatter premining topography than the Appalachian Basin region. This alternative would have long-term benefits, primarily in terms of soil reconstruction and stream restoration, of a relatively small geographic scope. Therefore, Alternative 2 would have a Minor Beneficial effect on the topography, geology, and soils of these regions.

4.2.3.4.2.6 Illinois Basin Region

Alternative 2 would result in a slight decrease in total coal production in this region, thereby decreasing the total acreage disturbed by mining each year. This decrease in acreage, combined with qualitative benefits in terms of landforming and soil restoration requirements, would have long-term positive impacts of a relatively small geographic scope. Therefore, Alternative 2 would have a Minor Beneficial effect on the topography, geology, and soils of this region.

4.2.3.4.2.7 Northern Rocky Mountains and Great Plains Region

Alternative 2 would result in a slight decrease in total coal production in this region, thereby decreasing the total acreage disturbed by mining each year. This decrease in acreage, combined with qualitative benefits in terms of soil salvage and reconstruction and streamside vegetative corridors, would have long-term positive impacts of a relatively small geographic scope. Therefore, Alternative 2 would have a Minor Beneficial effect on the topography, geology, and soils of this region.

4.2.3.4.2.8 Northwest and Western Interior Regions

Alternative 2 would have long-term qualitative benefits in terms of soil salvage and reconstruction and protection and establishment of streamside vegetative corridors, mostly in the Western Interior region. There is very little active mining in the Northwest region and mining is very limited in geographic scope in the Western Interior region. Therefore, Alternative 2 would have a Negligible effect on the topography, geology, and soils of the Western Interior and Northwest regions.

4.2.3.4.3 Alternative 3

4.2.3.4.3.1 Topography

Alternative 3 would allow mountaintop removal mining operations and steep-slope AOC variances, provided that they do not damage natural watercourses on or off the permit area. It would prohibit approval of a steep-slope AOC variance if the variance would result in placement of excess spoil in an intermittent or perennial stream. It also would require that mountaintop removal mining sites and sites with a steep-slope AOC variance be restored to AOC if the approved postmining land use is not implemented during the revegetation responsibility period.

Alternative 3 would require that landforming principles be applied to the surface configuration created by backfilling and grading, but they need not be applied to excess spoil fills. It would require use of digital terrain models to document premining and postmining surface configurations of the mined area, with the exception of remining operations and non-contiguous permits no more than 40 acres in size. Alternative 3 also would establish more stringent approval criteria for mining through streams and would require restoration of the ecological function of perennial and intermittent streams that are mined through.

These requirements should reduce some of the adverse topographic disturbances that result from mining.

4.2.3.4.3.2 Geology

Changes in coal production expected due to Alternative 3 are small relative to the overall level of mining activity. Alternative 3 would not differ significantly from the No Action Alternative in terms of geologic impacts.

4.2.3.4.3.3 Soils

Alternative 3 would require salvage and redistribution of all topsoil (the A and E horizons) and sufficient quantities of subsoil (B and C horizons) or other suitable materials to provide optimal rooting depths to restore premining land use capability or to comply with revegetation requirements. It also would require salvage of all native vegetation and other organic materials, including root balls, which must be redistributed in accordance with an approved plan developed by a qualified ecologist or similar expert. The expert would determine the amounts needed to promote reestablishment of native vegetation and soil flora and fauna.

Alternative 3 would allow use of selected overburden materials as substitutes for (or supplements to) topsoil or subsoil, but only if the operator demonstrates that: (1) the quality of the existing topsoil and subsoil is inferior to that of other overburden materials; or (2) the quantity of the existing topsoil and subsoil is insufficient to provide the optimal rooting depth or meet other plant growth requirements. In the latter case, all existing topsoil and favorable subsoil must be salvaged and redistributed. The operator also must demonstrate that the resulting soil medium would be more suitable than the existing topsoil and subsoil to sustain vegetation and that the selected overburden materials are the best available within the permit area for that purpose. The operator would have to redistribute soil materials in a manner that limits compaction and provides optimal rooting depth to support the approved plan for revegetation and reforestation.

These requirements should reduce some of the adverse soil effects, particularly those related to compaction and lack of an adequate root zone and suitable growing medium for reforestation that can result from mining under the No Action Alternative.

Impacts on topography, geology, and soils would vary by region. Each region is discussed separately below.

4.2.3.4.3.4 Appalachian Basin Region

Alternative 3 would cause a decrease in total coal production for this region, which should decrease the total area disturbed by mining each year. In terms of qualitative impacts, this Alternative would require use of landforming principles to design and construct the postmining surface configuration. It also would require that postmining soils be reconstructed with a root zone adequate to restore premining land use capability and fully support reforestation. Therefore, Alternative 3 would have long-term positive impacts of a medium geographic scope with a Minor Beneficial effect on the topography, geology, and soils of this region.

4.2.3.4.3.5 Colorado Plateau, Gulf Coast, Illinois Basin, Northern Rocky Mountains and Great Plains, and Western Interior Regions

Alternative 3 would result in in a slight decrease in total coal production in the Illinois Basin region, thereby decreasing the total acreage disturbed by mining each year. The other regions listed above would experience no measurable change in coal production under this Alternative. Qualitative benefits from landforming, soil salvage and restoration, and streamside vegetative corridor requirements would have long-term positive impacts of a small geographic scope with a Minor Beneficial effect on the topography, geology, and soils of these regions.

4.2.3.4.3.6 Northwest Region

There is very little active mining in the Northwest region. Therefore, Alternative 3 would have a Negligible effect on the topography, geology, and soils of this region.

4.2.3.4.4 Alternative 4

4.2.3.4.4.1 Topography

Alternative 4 would allow mountaintop removal mining operations and steep-slope AOC variances, provided that they do not damage natural watercourses on or off the permit area. It would prohibit approval of a steep-slope AOC variance if the variance would result in placement of excess spoil in an intermittent or perennial stream. It also would require that mountaintop removal mining sites and sites with a steep-slope AOC variance be restored to AOC if the approved postmining land use is not implemented during the revegetation responsibility period.

Alternative 4 would require that landforming principles be applied to the surface configuration created by backfilling and grading. It would require use of digital terrain models to document premining and postmining surface configurations of the mined area, with the exception of remining operations and non-contiguous permits no more than 40 acres in size. The final thickness of backfilled and graded spoil placed in the mined-out area could not vary from the combined premining thickness of overburden and the coal seam by more than ±20 percent at any point on the backfilled area. Alternative 4 also would establish more stringent approval criteria for mining through streams and would require restoration of the ecological function of perennial and intermittent streams that are mined through.

These requirements should reduce some of the adverse topographic disturbances that result from mining.

4.2.3.4.4.2 Geology

Changes in coal production expected due to Alternative 4 are small relative to the overall level of mining activity. Alternative 4 would not differ significantly from the No Action Alternative in terms of geologic impacts.

4.2.3.4.4.3 Soils

Alternative 4 would require salvage and redistribution of all topsoil (the A and E horizons) and sufficient quantities of subsoil (B and C horizons) or other suitable materials to provide optimal rooting depths to restore premining land use capability or to comply with revegetation requirements. Alternative 4 also would require salvage of all native vegetation and other organic materials, including root balls, which must be incorporated into the topsoil, redistributed on the surface of topsoiled areas, or used for stream restoration or fish and wildlife enhancement purposes.

Alternative 4 would allow use of selected overburden materials as substitutes for (or supplements to) either topsoil or subsoil, provided that the operator demonstrates that: (1) the quality of the existing topsoil and subsoil is inferior to that of other overburden materials; or (2) the quantity of the existing topsoil and subsoil is insufficient to provide the optimal rooting depth or meet other plant growth requirements. In the latter case, all existing topsoil and favorable subsoil must be salvaged and redistributed.

The operator also must demonstrate that the resulting soil medium would be more suitable than the existing topsoil and subsoil to sustain vegetation, and that the selected overburden materials are the best available within the permit area for that purpose. The operator would have to redistribute soil materials in a manner that limits compaction, and provides optimal rooting depth to support the approved plan for revegetation and reforestation.

These requirements should reduce some of the adverse soil effects, particularly those related to compaction and lack of an adequate root zone and suitable growing medium for reforestation that would result from mining under the No Action Alternative.

Impacts on topography, geology, and soils would vary by region. Each region is discussed separately below.

4.2.3.4.4.4 Appalachian Basin Region

Alternative 4 would cause a decrease in total coal production for this region, which should decrease the total area disturbed by mining each year. In terms of qualitative impacts, this alternative would require use of landforming principles to design and construct the postmining surface configuration and would place restrictions on how much the postmining elevation may differ from the premining elevation at any point in the backfilled and graded area. It also would require that postmining soils be reconstructed with a root zone adequate to restore premining land use capability and fully support reforestation. These rule elements would result in readily apparent benefits to geologic features and soils such as re-creating microclimates and ecological niches that were present prior to mining activities and may reduce erosion impacts in local and adjacent areas by preventing the creation of uniform slopes. Therefore, Alternative 4 would have long-term positive impacts of a medium geographic scope with a Moderate Beneficial effect on the topography, geology, and soils of this region.

4.2.3.4.4.5 Colorado Plateau, Gulf Coast, Illinois Basin, and Northern Rocky Mountains and Great Plains Regions

Alternative 4 would result in in a slight decrease in total coal production in the Illinois Basin region, thereby decreasing the total acreage disturbed by mining each year. The other regions listed above would experience no measurable change in coal production under this alternative. In terms of qualitative benefits, this alternative would result in readily apparent benefits to geologic features and soils from requirements such as landforming, soil salvage and restoration that would have long-term positive impacts by returning mined areas to a condition that was present prior to mining activities. The geographic scope of Alternative 4, however, is small and therefore, this Alternative is expected to have a Minor Beneficial effect on the topography, geology, and soils of these regions.

4.2.3.4.4.6 Northwest and Western Interior Regions

There is very little active mining in the Northwest and Western Interior regions. Changes in coal production expected due to Alternative 4 are small relative to this level of mining activity. Thus, Alternative 4 would have a Negligible effect on the topography, geology, and soils of these regions.

4.2.3.4.5 Alternative 5

Alternative 5 would apply only to surface and underground mining activities that result in placement of excess spoil outside the mined area or disposal of coal mine waste material in perennial or intermittent streams. These conditions predominantly exist in the Appalachian Basin region.

4.2.3.4.5.1 Topography

Alternative 5 would allow mountaintop removal mining operations and steep-slope AOC variances, provided that they do not damage natural watercourses on or off the permit area. It would prohibit approval of a steep-slope AOC variance if the variance would result in placement of excess spoil in an intermittent or perennial stream. It also would require that mountaintop removal mining sites and sites with a steep-slope AOC variance be restored to AOC if the approved postmining land use is not implemented during the revegetation responsibility period. It would require use of digital terrain models to document premining and postmining surface configurations of the mined area, with the exception of remining operations and non-contiguous permits no more than 40 acres in size. For those operations to which it applies, Alternative 5 also would establish more stringent approval criteria for mining through streams and would require restoration of the ecological function of perennial and intermittent streams that are mined through. These requirements should reduce some of the adverse topographic disturbances that result from mining by increasing the amount of mined areas that are returned to a condition that more closely resembles the general surface configuration of the land prior to mining and blends into and complements the drainage pattern of the surrounding terrain.

4.2.3.4.5.2 Geology

Changes in coal production expected due to Alternative 5 are small relative to the overall level of mining activity. Thus, Alternative 5 would not differ significantly from the No Action Alternative in terms of geologic impacts.

4.2.3.4.5.3 Soils

Alternative 5 would require salvage and redistribution of all topsoil (the A and E horizons) and sufficient quantities of subsoil (B and C horizons) or other suitable materials to provide optimal rooting depths to restore premining land use capability or to comply with revegetation requirements. It also would require salvage of all native vegetation and other organic materials, including root balls, which must be redistributed in accordance with an approved plan developed by a qualified ecologist or similar expert. The expert would determine the amounts needed to promote reestablishment of native vegetation and soil flora and fauna.

Alternative 5 would allow use of selected overburden materials as substitutes for (or supplements to) either topsoil and/or subsoil, provided that the operator demonstrates that: (1) the quality of the existing topsoil and subsoil is inferior to that of other overburden materials; or (2) the quantity of the existing topsoil and subsoil is insufficient to provide the optimal rooting depth or meet other plant growth requirements. In the latter case, all existing topsoil and favorable subsoil must be salvaged and redistributed.

The mine operator also must demonstrate that the resulting soil medium would be more suitable than the existing topsoil and subsoil to sustain vegetation and that the selected overburden materials are the best available within the permit area for that purpose. The operator would have to redistribute soils in a manner that limits compaction and provides optimal rooting depth to support the approved plan for revegetation and reforestation.

These requirements should reduce some of the adverse soil effects, particularly those related to compaction and lack of an adequate root zone and suitable growing medium for reforestation that can result from mining under the No Action Alternative.

Impacts on topography, geology, and soils would vary by region. Each region is discussed separately below.

4.2.3.4.5.4 Appalachian Basin Region

Alternative 5 would cause a slight decrease in total coal production for this region, which should decrease the total area disturbed by mining each year. In addition, the area disturbed per million tons of coal mined would decrease. The slope analysis indicates no change in topographic moderation compared to the results of the No Action Alternative. For those operations to which it applies, Alternative 5 would require that postmining soils be reconstructed with a root zone adequate to restore premining land use capability and fully support reforestation. Alternative 5 would have some long-term qualitative positive impacts, primarily in the area of soil salvage and reconstruction and streamside vegetative corridors, but the geographic scope of those impacts would be limited because the alternative would not apply to all operations. Therefore, it would have a Moderate Beneficial effect on the topography, geology, and soils of this region.

4.2.3.4.5.5 Other Regions

Alternative 5 would have a Negligible effect on the topography, geology, and soils of regions other than the Appalachian Basin region because very few operations in those regions dispose of excess spoil or coal mine waste outside the mined area, which means that very few operations in those regions would be subject to the requirements of this alternative.

4.2.3.4.6 Alternative 6

Alternative 6 would apply only to mining-related activities within 100 feet of an intermittent or perennial stream. It would establish more stringent approval criteria for mining through streams and would require restoration of the ecological function of perennial and intermittent streams that are mined through. The model mines analysis indicates that this alternative would have little impact on coal production, disturbance per million tons of coal removed, or postmining slope conditions relative to the No Action Alternative. In addition, Alternative 6 would not differ from the No Action Alternative with respect to requirements for soils and AOC restoration. Therefore, this alternative would have a Negligible effect on the topography, geology, and soils of all regions.

4.2.3.4.7 Alternative 7

Alternative 7 would apply only when certain conditions exist that warrant enhanced permitting conditions. For purposes of this FEIS, the model mines analysis assumes that this alternative would apply only to operations in steep-slope areas and to operations that place excess spoil or coal mine waste in perennial or intermittent streams.

4.2.3.4.7.1 Topography

Alternative 7 is identical to the No Action Alternative with respect to exceptions to AOC restoration requirements. For those operations to which Alternative 7 would apply, this alternative would require application of landforming principles to design and create the final surface configuration of the reclaimed mined area. It would require use of digital terrain models to document the premining and postmining surface configurations of the mined area, with the exception of remining operations and non-contiguous permits no more than 40 acres in size. The final thickness of backfilled and graded spoil placed in the mined-out area could not vary from the combined premining thickness of overburden and the coal seam by more than ±20 percent at any point on the backfilled area. Alternative 7 also would establish more stringent approval criteria for mining through streams and would require restoration of the ecological function of perennial and intermittent streams that are mined through.

These requirements should reduce some of the adverse topographic disturbances that results from mining.

4.2.3.4.7.2 Geology

Changes in coal production expected due to Alternative 7 are small relative to the overall level of mining activity. Alternative 7 would not differ significantly from the No Action Alternative in terms of geologic impacts.

4.2.3.4.7.3 Soils

Alternative 7 would require salvage and redistribution of all topsoil (the A and E horizons) and sufficient quantities of subsoil (B and C horizons) or other suitable materials to provide optimal rooting depths to restore premining land use capability or to comply with revegetation requirements. To the extent that this alternative would apply to an operation; i.e., to the extent that enhanced permitting conditions are required, Alternative 7 would require salvage of all native vegetation and other organic materials, including root balls, which must be incorporated into the topsoil, redistributed on the surface of topsoiled areas, or used for stream restoration or fish and wildlife enhancement purposes.

Alternative 7 would allow use of selected overburden materials as substitutes for (or supplements to) either topsoil and/or subsoil, provided that the operator demonstrates that: (1) the quality of the existing topsoil and subsoil is inferior to that of other overburden materials; or (2) the quantity of the existing topsoil and subsoil is insufficient to provide the optimal rooting depth or meet other plant growth requirements. In the latter case, all existing topsoil and favorable subsoil must be salvaged and redistributed.

The mine operator also must demonstrate that the resulting soil medium would be more suitable than the existing topsoil and subsoil to sustain vegetation and that the selected overburden materials are the best available within the permit area for that purpose. The operator would have to redistribute soils in a manner that limits compaction and provides optimal rooting depth to support the approved plan for revegetation and reforestation.

These requirements should reduce some of the adverse soil effects, particularly those related to compaction and lack of an adequate root zone and suitable growing medium for reforestation that can result from mining under the No Action Alternative.

Impacts on topography, geology, and soils would vary by region. Each region is discussed separately below.

4.2.3.4.7.4 Appalachian Basin Region

Alternative 7 would cause a slight decrease in total coal production for this region, which should decrease the total area disturbed by mining each year. In addition, the area disturbed per million tons of coal mined would decrease. The model mines slope analysis indicates no change in topographic moderation compared to the results of the No Action Alternative. For those operations to which it applies, Alternative 7 would require that postmining soils be reconstructed with a root zone adequate to restore premining land use capability and fully support reforestation. Alternative 7 would have some long-term qualitative positive impacts, primarily in the area of soil salvage and reconstruction and streamside vegetative corridors, but the geographic scope of those impacts would be limited because the alternative would not apply to all operations. Therefore, it would have a Moderate Beneficial effect on the topography, geology, and soils of this region.

4.2.3.4.7.5 Other Regions

Alternative 7 would have a Negligible effect on the topography, geology, and soils of regions other than the Appalachian Basin region because very few operations in those regions dispose of excess spoil or coal mine waste outside the mined area, which means that very few operations in those regions would be subject to the requirements of this alternative.

4.2.3.4.8 Alternative 8 (Preferred)

4.2.3.4.8.1 Topography

Alternative 8 (Preferred) would allow mountaintop removal mining operations, provided that they do not damage natural watercourses on or off the permit area. It would define damage in terms of parameters of concern, peak flows, and total flow volumes. This alternative would allow steep-slope AOC variances needed to achieve specified postmining land uses, but prohibit approval of a steep-slope AOC variance if the variance would result in placement of excess spoil in an intermittent or perennial stream. It also would require that mountaintop removal mining sites and sites with a steep-slope AOC variance be restored to AOC if the approved postmining land use is not implemented during the revegetation responsibility period.

Alternative 8 (Preferred) would require that landforming principles be applied to the surface configuration of the top deck of excess spoil fills. While use of landforming principles would not be required for reclamation of the mined area itself, this alternative would require that the postmining drainage pattern of perennial, intermittent, and ephemeral streams restored after mining be similar to the premining drainage pattern, with exceptions for stability, fish and wildlife enhancement, and prevention of downcutting of stream channels. Alternative 8 (Preferred) also would establish more stringent approval criteria for mining through streams and would require restoration of the ecological function of perennial and intermittent streams that are mined through.

These requirements should reduce some of the adverse topographic disturbances that result from mining.

4.2.3.4.8.2 Geology

Changes in coal production expected due to Alternative 8 are small relative to the overall level of mining activity. Alternative 8 (Preferred) would not differ significantly from the No Action Alternative in terms of geologic impacts.

4.2.3.4.8.3 Soils

Alternative 8 (Preferred) would require salvage and redistribution of all topsoil (the A and E horizons) and sufficient quantities of subsoil (B and C horizons) or other suitable materials to provide optimal rooting depths to restore premining land use capability or to comply with revegetation requirements. It also would require salvage of all native vegetation and other organic materials, including root balls, which must be incorporated into the topsoil, redistributed on the surface of topsoiled areas, or used for stream restoration or fish and wildlife enhancement purposes.

Alternative 8 (Preferred) would allow use of selected overburden materials as substitutes for (or supplements to) either topsoil and/or subsoil, provided that the operator demonstrates that: (1) the quality of the existing topsoil and subsoil is inferior to that of other overburden materials; or (2) the quantity of the existing topsoil and subsoil is insufficient to provide the optimal rooting depth or meet other plant growth requirements. In the latter case, all existing topsoil and favorable subsoil must be salvaged and redistributed.

The mine operator also must demonstrate that the resulting soil medium would be more suitable than the existing topsoil and subsoil to sustain vegetation and that the selected overburden materials are the best available within the permit area for that purpose. The operator would have to redistribute soils in a manner that limits compaction and provides optimal rooting depth to support the approved plan for revegetation and reforestation.

These requirements should reduce some of the adverse soil effects, particularly those related to compaction and lack of an adequate root zone and suitable growing medium for reforestation that can result from mining under the No Action Alternative.

These requirements should reduce some of the adverse soil effects, particularly those related to compaction and lack of an adequate root zone and suitable growing medium for reforestation that can result from mining under the No Action Alternative.

Impacts on topography, geology, and soils would vary by region. Each region is discussed separately below.

4.2.3.4.8.4 Appalachian Basin Region

Alternative 8 (Preferred) would cause a slight decrease in total coal production for this region, which should result in a slight decrease in the total area disturbed by mining each year. In addition, the analysis indicates that the area disturbed per million tons of coal mined would decrease. With respect to topography, the model mines slope analysis indicates that this alternative would result in less topographic moderation than the No Action Alternative, which means that the postmining surface configuration would more closely resemble the premining configuration. This Alternative also would require that postmining soils be reconstructed with a root zone adequate to restore premining land use capability and fully support reforestation. Therefore, Alternative 8 (Preferred) would have long-term positive impacts of a medium geographic scope with a Moderate Beneficial effect on the topography, geology, and soils of this region.

4.2.3.4.8.5 Colorado Plateau, Gulf Coast, and Northern Rocky Mountains and Great Plains Regions

The regions listed above would experience no measurable change in coal production under Alternative 8 (Preferred). Qualitative benefits from landforming, soil salvage and restoration, and streamside vegetative corridor requirements would have long-term positive impacts of a small geographic scope with a Minor Beneficial effect on the topography, geology, and soils of these regions.

4.2.3.4.8.6 Illinois Basin Region

Alternative 8 (Preferred) would result in in a slight decrease in total coal production in this region, thereby decreasing the total acreage disturbed by mining each year. Qualitative benefits from landforming, soil salvage and restoration, and streamside vegetative corridor requirements would have long-term positive impacts of a small geographic scope with a Minor Beneficial effect on the topography, geology, and soils of this region.

4.2.3.4.8.7 Northwest and Western Interior Regions

There is very little active mining in the Northwest and Western Interior regions. Therefore, Alternative 8 (Preferred) would have a Negligible effect on the topography, geology, and soils of these regions.

4.2.3.4.9 Alternative 9

Alternative 9 would require the repromulgation of the currently vacated 2008 Stream Buffer Zone rule. This Alternative would require minimization of excess spoil generation, place limits on excess spoil fill capacity to match the anticipated amount of excess spoil to be generated, and prohibit mining activities in or within 100 feet of an intermittent or perennial stream unless the applicant demonstrates and the regulatory authority finds that avoidance is not reasonably possible. The model mines analysis indicates that the impacts of Alternative 9 would not differ significantly from those of the No Action Alternative because the Clean Water Act requirements and policies discussed in the Regulatory Impact Analysis for this rulemaking and the state AOC and excess spoil policies identified in Section 4.2.3.1 of this FEIS have effectively achieved implementation of this Alternative in Central Appalachia, which is the region in which the 2008 Stream Buffer Zone rule would have had its greatest impact if it had remained in effect. Therefore, if repromulgated, Alternative 9 would now have Negligible effects on topography, geology, and soils.

4.2.3.5 Potential Minimization and Mitigation Measures

The Action Alternatives are not expected to result in any negative environmental consequences for topography, geology, and soils. Therefore, identifying potential minimization and mitigation measures is not applicable for this analysis.

4.2.4 Air Quality, Greenhouse Gas Emissions, and Climate Change

This section characterizes the impacts of the Alternatives on air quality. The discussion is organized as follows:

- Section 4.2.4.1 describes the existing regulatory environment and its implications for the No Action Alternative;
- Section 4.2.4.2 describes key elements of Action Alternatives and their effect on air quality and greenhouse gas emissions;
- Section 4.2.4.3 describes the methods employed to evaluate potential effects to air resources;
- Section 4.2.4.4 presents the results of this evaluation;
- Section 4.2.4.5 summarizes results across Action Alternatives; and
- Section 4.2.4.6 describes potential minimization and mitigation measures.

This section does not detail public health and safety associated with coal mining-related air pollution; health effects are discussed in Section 4.3.4 of this document.

OSMRE is limited in its ability to regulate air quality. Air emissions permits for coal mines fall under the authority of the Clean Air Act (CAA) and are not issued under SMCRA. The decision discussed in *In re Permanent Surface Min. Regulation Litig. I, Round II*, 1980 U.S. Dist. LEXIS 17660 at *43-44 (D.D.C., May 16, 1980), 19 Env't Rep. Cas. (BNA) 1477, clarifies that OSMRE does not have jurisdiction over industrial emissions, and that its jurisdiction is limited to air pollution attendant to wind and water erosion (e.g., exposing soil to wind causing particulates to become airborne). The decision clarifies that all other mining-related emissions are generally regulated under the CAA and not SMCRA.

The following discussion examines air quality as a resource within the human environment, focusing on the specific components that coal mining operations can influence, and does not limit the discussion to what OSMRE is specifically authorized to regulate (i.e., erosion-related air pollution). In addition, the following discussion describes expected changes in greenhouse gas emissions from reductions in overall levels of coal mining and combustion activities. These evaluations provide the required basis (40 CFR 1502.16) for a scientific and analytic comparison between the Alternatives.

This section focuses primarily on the potential air quality and greenhouse gas emissions impacts of coal mining operations according to the Alternatives being considered (including the No Action Alternative). The Alternatives may influence air quality in the following ways:

- Changes in overall emissions levels that may result from shifts in coal production levels. The predominant effect of the Action Alternatives on greenhouse gas emissions is the reduction in carbon dioxide (CO_2) emissions from coal combustion. In addition, reductions in coal production generates changes in methane (CH_4) emissions released when coal is extracted (i.e., "fugitive emissions"), as well as changes in emissions associated with activities undertaken through the course of operations (i.e., emissions from vehicle use and release of toxics from explosives detonation).
- Additional requirements for reforestation, revegetation, and streamside vegetative corridors may increase the terrestrial carbon sequestration potential of the postmining landscape
- Changes in the extent equipment and vehicles are used affects combustion engine emissions from coal mining; and
- Changes in dust or particulates from burning or wind erosion of materials used and/or soil being exposed on site during coal mining.

4.2.4.1 Effects of the Current Regulatory Environment (the No Action Alternative)

As discussed in Chapter 3, air emissions emanate from vehicle engines associated with the mining activity, from emissions released during explosives detonation, from the erosion and wind transport of dust and particulate matter, and from the release of greenhouse gases as coal is exposed. Under the No Action Alternative, the effects of coal mining on air quality, with the exception of erosion-related pollution, are regulated primarily under the CAA. Implementation of performance standards for blasting, however, also falls under the purview of SMCRA. Compliance with these standards reduces human exposure to toxic air pollutants that may otherwise result from blasting.

Pollutants released from combustion engines include five of the six EPA defined criteria pollutants: carbon monoxide, sulfur dioxide, nitrogen oxides, volatile organic compounds (VOCs), and particulate matter (PM_{10} and $PM_{2.5}$). EPA regulates toxic emissions from mobile sources through standards on fuels and engine efficiency; however, mobile sources do not require permitting under the CAA and methane emissions from mobile sources are not subject to performance standards.

The detonation of explosives under ideal field conditions releases nitrogen gas, carbon dioxide (CO_2), and water vapor. In the case that field conditions are not ideal, or the explosives product formulation is incorrect, the blast may yield nitric oxide, nitrogen dioxide, or carbon monoxide in addition to the gases listed above. Section 515 of SMCRA (30 U.S.C. § 1265(b)(15)) includes a general performance standard that requires limitation of the type and size of explosives and detonating equipment, and timing of the detonation, to prevent injury to persons and damage to property (e.g. livestock) outside the permit area.

The regulations implementing this section of SMCRA are included in the performance standards at 30 CFR 816/817.67. Specifically, 30 CFR 816/817.67(a) provides general regulatory requirements for control of adverse effects from conducting blasting operations, including the requirement to prevent injury to persons and damage to property. Subsequent subsections address specific adverse effects of blasting which include airblast, flyrock, and ground vibrations; however, fumes are not addressed. In addition, 30 CFR 780.13 requires that blast plans describe how blasting will be conducted to meet the performance standards. In the case that concern exists regarding potential danger from fumes to people or property, the regulatory authority may require that blasting be conducted to minimize fume generation or blast area security be expanded to ensure exposure is avoided.

While ground vibrations, airblast, and flyrock are commonly identified in the blast plan, blasting fumes are only addressed under certain circumstances, by a handful of state regulatory authorities. If not addressed in the blast plan, any visible fumes observed during an inspection or reported by a citizen that approach people or living property are considered “imminent harm” (30 CFR 843.11). Industry practice is to never enter a reddish-orange cloud as it is considered toxic and thus poses an imminent danger. Historically, though infrequent, RAs have issued Notices of Violation and imminent harm Cessation Orders through the state counterpart regulations to 30 CFR Part 843.

On April 18, 2014, OSMRE received a petition for rulemaking from WildEarth Guardians requesting that OSMRE “promulgate a rule prohibiting the production of visible nitrogen oxide emissions during blasting at surface coal mining operations in order to protect public and mine worker health, welfare, and safety, and prevent injury to persons, as required by the Surface Mining Control and Reclamation Act of 1977 (SMCRA).” On July 25, 2014, OSMRE published the petition in the Federal Register (79 FR 43326). On February 20, 2015, the Director’s decision to grant the petition in principle was published (80 FR 9256). OSMRE is currently developing a proposed rule that would require the regulatory authority to consider protections for persons and private property with regard to fume generation from blasting operations.

Coal mining may also affect particulate matter concentrations in air, specifically fugitive dust. Dust may be released or spread through operations due to wind during mining activities such as blasting; operation of drag lines; hauling overburden and mined coal; and road grading as well as in general from earthmoving activities (Lashof et al., 2007). As noted previously, if related to erosion and wind transport, fugitive dust is regulated under SMCRA, otherwise it is regulated under the CAA or local ordinances. This type of dust is generally coarse (PM_{10} classification). Surface mining produces more PM_{10} emissions in comparison to underground mining as a result of the increased percentage of disturbance occurring aboveground (Lashof et al., 2007).

Section 515 of SMCRA (30 U.S.C. § 1265(b)) contains provisions related to prevention of windborne erosion from stockpiled and transported materials, as well as provisions related to handling vegetative debris. Moreover, SMCRA’s implementing regulations at 30 CFR -816.95(a) and 817.95(a) require that all exposed surface areas be protected and stabilized to control erosion. Likewise, §§ 816.150(b)(1) and 817.150(b)(1) require the control or prevention of erosion (including road dust) through measures such as vegetating, watering, using chemical or other dust suppressants, or otherwise stabilizing all exposed surfaces.

However, neither SMCRA nor the implementing regulations specifically require reincorporation of plant debris accumulated from site clearing (for example non-merchantable trees, tree limbs, stumps and branches). As a result these materials are often burned on-site, which may impact local air quality from the addition of particulate matter into the air. SMCRA and the implementing regulations require reforestation of previously forested mine sites unless the permittee has sought and received authorization to implement an alternative post mining land use. Coal regions are currently experiencing a net loss of forested area due to coal mining. This reduction in forested acreage impacts the environment in many ways; specific to air quality it results in the loss of oxygen production potential from the vegetation, and the net loss of sequestered carbon stocks. That is, forest-based carbon is reintroduced to the atmosphere as greenhouse gases from burning of the wood, rather than reincorporated into other stable uses (such as building materials), returned to the soil, or disposed of in ways that prevent carbon decay (e.g., landfilling).

In addition to the air quality impacts from operations at coal mines (from vehicles, blasting, and dust), the greenhouse gas methane may be released as the overburden is removed and coal and rock layers are broken as part of the mining process. Underground coal mining releases more fugitive methane than surface mining because of the higher gas content of deeper seams (Irving and Tailakov, 1999). Methane released from underground mines may be captured and used as an energy source. The objective of the U.S. EPA Coalbed Methane Outreach Program is to promote the recovery and use of coal mine methane by working with industry. Future voluntary involvement in this activity on the part of coal operations is uncertain. However, to the extent that participation grows over time, methane emissions associated with coal mining may decrease in the future under the No Action Alternative.

Finally, coal mining activity under the No Action Alternative reduces the terrestrial carbon sequestration potential of the landscape by reducing vegetative biomass, at least in the short term. The No Action Alternative requires the establishment of vegetative cover, but not reforestation. As a result, mined areas experience a net loss of forestland. In comparison to other vegetation, forested areas contain more biomass both above and below ground. This increased biomass represents additional carbon storage, additional CO_2 consumption during photosynthesis, and increased production of oxygen. The reduction in forested landscapes under the No Action Alternative reduces the level of carbon that is removed from the atmosphere, thus contributing to climate change.

Under the No Action Alternative, air emissions and air quality impacts from coal mining would continue to be regulated under the CAA, and to a lesser extent SMCRA, and would continue to fluctuate with coal mining methods and activity levels. For a more complete discussion of the CAA, please refer to Section 3.6.

4.2.4.1.1 Emissions from Coal Combustion

In 2015, electrical power generation accounted for approximately 91 percent of U.S. coal consumption, with the remainder used in a variety of industrial applications.[33] Electrical power generation includes public utilities that feed electricity to the general power grid, as well as dedicated power plants that generate electricity for specific industrial operations and other commercial facilities. At each generating facility, coal is burned to produce steam (coal combustion), which is used to rotate turbines and generate power. In 2015, coal-fired sources generated approximately 33 percent of all electricity produced in the U.S. (U.S. EIA, 2016d). This has declined 15 percent since 2011, due to the declining price of natural gas, a competing fuel source, environmental regulatory compliance, and other market factors (U.S. EIA, 2016c).

In general, coal combustion generates several principal pollutants that have been linked to adverse air quality impacts:

- **Carbon Dioxide**: Coal combustion produces CO_2, the primary greenhouse gas emission from the burning of fossil fuels (coal, oil, and natural gas). According to the U.S. EPA Greenhouse Gas Inventory Report, fossil fuel combustion accounted for 94 percent of total CO_2 emissions in the U.S. (approximately 5.7 billion short tons) in 2014. In the same year, coal combustion accounted for approximately 32 percent of total CO_2 emissions from fossil fuels (1.8 billion short tons) (U.S. EPA, 2016b).
- **Sulfur Dioxide**: EPA estimates that about 73 percent of sulfur dioxide (SO_2) emissions derive from combustion of fossil fuels at power plants. In addition to being one of the primary causes of acid rain, SO_2 can have negative health impacts from acute or chronic over exposure. Some health impacts include adverse respiratory effects, including bronchoconstriction and increased asthma symptoms. SO_2 inhalation has been shown to result in irritation of mucous membranes of the eyes and nose and may also affect the mouth, trachea, and lungs (VCAPCD, 2003).
- **Nitrogen Oxides**: Power generation is the second largest anthropogenic source (behind mobile sources) of nitrogen dioxide (NO_2) and other related nitrogen oxides (NOx). NOx is a key constituent in the formation of ground-level ozone, the main component of smog and has adverse effects on respiratory systems, causing or aggravating respiratory illnesses such as bronchitis and asthma but also increasing breathing difficulty even in healthy persons (VCAPCD, 2003).
- **Mercury**: EPA estimates that coal-fired power plants accounted for over half of all anthropogenic mercury emissions in the U.S. in 2005. After being emitted into the air, mercury can be deposited to land and eventually water, where it can enter the food chain. Birds and mammals that eat fish are more exposed to mercury than other animals, and mercury can bio-accumulate at higher levels of the food chain. At high levels of exposure, methyl mercury causes harmful effects on animals include death, reduced reproduction, slower growth and development, and abnormal behavior. In humans, mercury exposure at high levels can harm the brain, heart,

[33] Nearly all coal burned in the U.S. is produced domestically. The EIA reports that in 2014, only one percent of all coal consumed in the U.S. was imported. U.S. coal exports, however, have grown significantly in recent years. The EIA reports that from 2000 to 2010, coal producers exported about five percent of their product; in 2012, exports had grown to 12 percent, or 126 million short tons. In 2013 exports declined to 118 million short tons and in 2014 exports declined further to 97 million tons.

kidneys, lungs, and immune system. Research shows that moderate fish consumption is not a health concern. However, high levels of methyl mercury in the bloodstream of unborn babies and young children may harm the developing nervous system, impairing cognitive functions (U.S. EPA, 2014d).

Recent regulatory efforts have focused on the need to control emissions from power plants. The Mercury and Air Toxics Standards (MATS) rule establishes emission limits for mercury and other air pollutants from U.S. power plants. The Cross-state Air Pollution Rule (CSAPR) requires power plants in 27 states to reduce emissions that contribute to ambient ozone and/or fine particle pollution; EPA finalized the rule in 2011, and implementation began in 2012. In September 2016, the EPA finalized an update to the Cross-State Air Pollution Rule (CSAPR) for the 2008 ozone National Ambient Air Quality Standards (NAAQS); this rule will reduce summertime nitrogen oxides emissions from power plants in 22 states in the eastern U.S. Recent Supreme Court decisions verified EPA's authority to regulate greenhouse gas emissions. In August 2015, the EPA promulgated the Carbon Pollution Standards which limit emissions of CO_2 from new, modified, and reconstructed fossil-fuel fired power plants. At the same time, it promulgated the Clean Power Plan, which established guidelines for reducing CO_2 emissions from existing fossil-fuel fired power plants. States are charged with developing plans that will meet the emission performance rates (or equivalent state goals). EPA and industry analysts anticipate that many of the reductions will be met through shifting generation to less carbon-intensive sources of energy. On February 9, 2016 the Supreme Court stayed implementation of the Clean Power Plan pending judicial review.

4.2.4.2 Action Alternatives and Potential Effects on Air Quality, Greenhouse Gas Emissions, and Climate Change

This section identifies the aspects of the Action Alternatives expected to affect air emissions as a result of coal mining and related activities. While the elements of the Action Alternatives as described in Chapter 2 do not directly address air emissions from coal mining activities, implementation of the Action Alternatives may indirectly affect air quality. The requirements of Alternative 9 are not functionally different than the No Action Alternative; most current mining practices are consistent with the now-vacated 2008 SBZ rule and, accordingly, effects of Alternative 9 on air quality are anticipated to be Negligible. All other Action Alternatives have the potential to affect air quality in the following ways:

- Changes in the amount of earth moving (haulage) required may affect the extent of wind transport of dust ($PM_{2.5}$ and PM_{10}), as well as emissions from mobile sources (combustion engines): For instance, some Alternatives may require additional movement of surface material around a site, which would be expected to increase vehicle use on some sites. Vehicles are sources of nitrogen oxides (NO_x), CO_2, and particulate matter emissions. Thus, rule elements found in some Action Alternatives may result in increases in air emissions on a per-mine basis. On the other hand, some Action Alternatives reduce overall levels of coal production, which may reduce the generation of dust and emissions from mobile sources.
- Revegetation and reforestation requirements, as well as requirements to reduce burning of vegetation and other organic materials may reduce the wind transport of dust and increase the terrestrial carbon sequestration potential of the landscape: More stringent requirements for reforestation and revegetation of the postmining landscape reduce the extent to which materials

are exposed to wind transport and increase the availability of biomass to sequester carbon from the atmosphere. Increased terrestrial carbon sequestration may have a mitigating effect on the level of greenhouse gases in the atmosphere contributing to climate change. In addition, prohibitions on burning of vegetation and organic matter under the Action Alternatives reduce airborne particulates. Section 4.2.2.2 describes the potential climate stabilization benefits associated with reforestation requirements of the Action Alternatives.

Although the Action Alternatives do not directly regulate coal combustion, the collective effects of the elements of the Alternatives on the costs of coal mining are expected to marginally reduce coal production levels and have a consequent benefit in terms of a reduction in greenhouse gas emissions from coal burning. To provide perspective on the potential effects of the Alternatives on climate change, this analysis evaluates changes in greenhouse gas emissions as follows:

1. **Changes in CO_2 emissions:** Although the effect of the Action Alternatives on coal production is minor (less than one percent), this generates a net reduction in CO_2 emissions from fossil fuel combustion nationally. This analysis estimates how reductions in coal combustion, and increased production of substitute sources (e.g., natural gas), affects greenhouse gas emissions.
2. **Changes in CH_4 emissions:** The quantified change in methane emissions accounts for fugitive emissions from field production of coal (associated with reduced production) and natural gas (associated with increased production), as well as emissions from vehicle and equipment use, and transportation and storage.

Table 4.2-28 summarizes the various rule elements incorporated into the Action Alternatives that may affect air quality. The remainder of this section describes the potential direction and magnitude of the expected impacts in each of the coal regions.

Table 4.2-28. Action Alternative Elements and Potential Effects on Air Quality, Greenhouse Gases, and Climate Change

Action Alternative Element	Criteria Pollutants and Greenhouse Gases
Baseline Data Collection and Analysis	
Monitoring During Mining and Reclamation	
Definition of Material Damage to the Hydrologic Balance	
Evaluation Thresholds	
Stream Definitions	
Mining Through Streams	■
Activities In or Near Streams Including Excess Spoil and Coal Refuse	■
AOC Variances	■
Surface Configuration	■
Revegetation, Topsoil Management, and Reforestation	■
Fish and Wildlife Protection and Enhancement	■

The "Criteria Pollutants and Carbon Dioxide" column identifies Action Alternative elements that may: 1) result in additional earthmoving activities, thereby increasing the production of particulate matter and emissions of criteria pollutants from operation of vehicles and other equipment; and/or 2) result in additional vegetated land cover (e.g., reforestation) thereby reducing wind erosion of materials and increasing the terrestrial carbon sequestration potential of the landscape. In addition to the direct effects of the Action Alternative elements on criteria pollutants and greenhouse gas emissions, indirect impacts on CO_2, methane, and other emissions are also expected. While not associated with any particular rule element, the collective cost burden of implementing the Alternatives may change overall levels of coal production, thus affecting the levels of greenhouse gases and other air pollutants emitted through the course of coal mining activities and coal combustion. The predominant change in greenhouse gas emissions is due to the anticipated reduction in coal combustion. As previously noted, coal combustion is a significant source of emissions of CO_2 nationally. To the extent that decreased coal production results in decreased coal combustion, and increased energy production from substitute sources with lower emissions rates, such as natural gas, this could result in a net national reduction in CO_2 emissions as compared to the No Action Alternative. In addition, removing overburden to extract coal results in fugitive methane emissions. Consequently, increasing or reducing the level of mining activity likewise increases or reduces fugitive methane emissions. The EPA inventory of underground mine greenhouse gas emissions indicates that methane accounts for nearly all greenhouse gas emissions from underground mines; specifically fugitive methane emissions are significantly greater than CO_2 and nitrous oxide emissions from vehicles and equipment (U.S. EPA, 2013e). Reductions in coal production levels may also reduce toxic pollutant emissions from blasting activities.

4.2.4.2.1 Protection of the Hydrologic Balance

The elements of the Action Alternatives that are focused on the protection of the hydrologic balance are not expected to directly affect air quality for the reasons described below. As noted previously, however, the collective burden of implementing all of the elements of the Action Alternatives (other than Alternative 9), including those related to protection of the hydrologic balance, is expected to change the overall level of coal mining activity (i.e., increased costs of coal production decreases overall production levels). In addition, in the case of Alternative 2, the cost of surface mining methods results in a slight shift toward additional underground mining methods, which emit more methane than surface methods. As a result, the Action Alternatives (excluding Alternative 9) may all affect greenhouse gas emissions, primarily methane, and other emissions (e.g., from vehicles and blasting) released through the course of coal mining.

4.2.4.2.2 Baseline Data Collection and Analysis

Baseline data collection and analysis are focused on water sampling procedures and are not expected to affect air resources under the Action Alternatives.

4.2.4.2.3 Monitoring During Mining and Reclamation

Additional monitoring requirements are focused on water quality effects and are not expected to influence air resources under the Action Alternatives.

4.2.4.2.4 Definition of Material Damage to the Hydrologic Balance

The lack of definition of *material damage to the hydrologic balance* under the No Action Alternative, and the implementation of the proposed definition under Action Alternatives 2, 3, 4, and 8 (Preferred) is not expected to affect air quality effects of mining activities.

4.2.4.2.5 Evaluation Threshold

Evaluation thresholds are monitoring standards set lower than those for material damage to the hydrologic balance and are designed to act as a type of early warning system to prevent material damage from being reached. These evaluation thresholds would not impact air quality directly as they do not establish thresholds related to air emissions.

4.2.4.2.6 Activities In or Near Streams

The elements of the Action Alternatives focused on activities in or near streams may affect air pollutant emissions from coal mining both directly through their implementation and indirectly as their implementation contributes to overall shifts in coal production levels. The indirect effect here again refers to the Action Alternatives (excluding Alternative 9) increasing the cost of coal production such that overall production levels, and associated air pollutant emissions, change. The following text describes how the elements regulating activities in or near streams more directly affect air quality.

4.2.4.2.7 Stream Definitions

Alternatives 2, 4, 7, and 8 (Preferred) specify a change in how streams are defined as intermittent, ephemeral, or perennial, and therefore, what mining activities may occur in or near a given stream. This rule element is not expected to itself affect air quality impacts of coal mining.

4.2.4.2.8 Mining through Streams

The No Action Alternative allows diversion of intermittent and perennial streams where the regulatory authority finds that the diversion will not adversely affect the water quality and quantity and related environmental resources of the stream. The No Action Alternative also requires restoration of perennial and intermittent streams to restore or approximate the premining characteristics of the original stream channel, including natural streamside vegetation. The Action Alternatives further specify how mining through streams and associated stream restoration should be implemented. Related to air quality, this element dictates establishment of 100-foot forested or appropriately-vegetated stream corridors (Alternatives 2, 7, and 8 (Preferred)). Additional vegetated land cover has the potential to increase the terrestrial carbon sequestration potential of the landscape, thereby mitigating potential effects of climate change. In addition, additional vegetated land cover reduces the amount of material vulnerable to wind transport.

4.2.4.2.9 Activities In or Near Streams, Including Excess Spoil and Coal Refuse

The Action Alternatives address mining activities, such as placement of excess spoil and coal mine waste, in or within 100 feet of streams. In limiting placement of excess spoil fills and refuse piles, the Action Alternatives (excluding Alternative 9) may increase the hauling distance for, and therefore air pollutant emissions associated with, the vehicles transporting excess spoil. The degree to which emissions are affected is difficult to quantify as it depends upon site-specific and permit-specific factors. In general, however, longer distances and additional operating time may increase emissions of nitrous oxide, CO_2, and particulate matter emissions from mining-related haulage vehicles, relative to the No Action Alternative. This effect, however, may be mitigated by overall reductions in coal production levels under the Action Alternatives, which may produce a countervailing effect of reducing the use of equipment and vehicles.

4.2.4.2.10 Approximate Original Contour

The elements of the Action Alternatives related to AOC variance and surface configuration may affect air quality by increasing emissions from equipment and vehicles. As with the other rule elements, they also contribute to increasing the costs of coal mining activities and the consequent shifts in coal production levels and methods. As previously described emissions associated with coal mining may change proportionally to the overall levels of surface and underground production.

4.2.4.2.11 AOC Variances

SMCRA generally requires the return of the landscape to AOC and the original configuration. Variances to AOC are allowed for mountaintop removal and steep slope mining, common practices in the Appalachian Basin region. Under the No Action Alternative, for both mountaintop removal and steep-slope mining, beneficial postmining land use (PMLU) must be achieved, with equal or better use demonstrated. For steep-slope mining, requests to deviate from AOC do not currently require demonstration that deviations from AOC are necessary for the identified PMLU.

Fewer allowed variances from AOC could occur under the Action Alternatives (excluding Alternatives 6, 7, and 9), which would result in increased need for material handling and movement on the mine site. This would increase heavy equipment and vehicle use, and therefore the associated vehicle-related air emissions. Additional handling of the materials could also result in increased wind-born particulates during landforming.

4.2.4.2.12 Surface Configuration

Premining surface configuration guides topography reclamation requirements, both during mining and during postmining reclamation. This entails the use of landform measurements and terrain modeling to confirm premining topography adherence. Some Action Alternatives require that the backfilled areas of a mine not vary from their premining elevation/slope by ±20 percent (the difference between premining surface elevation and the bottom elevation of the lowest coal seam mined). Conditions would be documented by digital terrain models, both before mining and during backfilling. The relevant Action Alternatives may allow the placement of excess spoil in streams only with stringent provisions.

Similar to the AOC variances element, the proposed landforming requirements may result in increased use of equipment and vehicles on mine sites to create the required postmining topography. While the magnitude of this effect would be site-specific, emissions would increase with increased vehicle use. However, reductions in overall levels of coal production under the Action Alternatives may serve to offset this potential effect by reducing the level of equipment and vehicle use.

4.2.4.2.13 Revegetation, Soil Management, and Reforestation

Requirements for reforestation, vegetation, and topsoil management, may benefit air quality by increasing the terrestrial carbon sequestration potential of the landscape and by reducing the amount of time materials are exposed to wind erosion, thereby reducing particulate matter. In addition, these elements contribute to the increased cost of coal mining activities, affecting mining-related emissions by shifting coal production levels or methods.

Postmining land cover is directed by the revegetation, topsoil management, and reforestation elements of the Alternatives. As described under the No Action Alternative, while establishing vegetative cover is required after mining, reforestation is not currently universally required. Under the Action Alternatives except for Alternatives 6 and 9, the revegetation of reclaimed lands must be completed using only native species; the use of overburden materials as a replacement for, or as a supplement to, topsoil requires greater justification; available organic materials must be incorporated into the revegetation process; and reforestation of previously forested areas is required. These changes serve primarily to return the postmining land to a native forest ecosystem as quickly as possible. This has two effects on air quality by: 1) potentially limiting particulate matter by reducing the time materials are exposed to wind erosion, and 2) increasing the terrestrial carbon sequestration capacity of the landscape. In addition, Alternatives 2, 3, 4, 5, and 7 all include some level of prohibition on burning of vegetation and other organic materials, reducing the amount of airborne particulate matter from mining operations.

4.2.4.2.14 Fish and Wildlife Protection and Enhancement

Fish and Wildlife Protection and Enhancement elements related to air quality include the provisions for establishing streamside vegetative corridors. Requirements for fish and wildlife protection and enhancement may benefit air quality by increasing the terrestrial carbon sequestration potential of the landscape and by reducing the amount of time materials are exposed to wind erosion, thereby reducing particulate matter. In addition, these elements contribute to the increased cost of coal mining activities, affecting mining-related emissions by shifting coal production levels or methods.

Specifically, the Action Alternatives (excluding Alternative 9) include a specified width requirement for streamside vegetative corridors. Alternatives 2, 5, 6, 7 and 8 (Preferred) require creation of a 100-foot streamside vegetative corridor comprising native, non-invasive species along ephemeral, intermittent, or perennial streams restored or permanently diverted. Alternatives 3 and 4 generally require establishment of a 300-foot streamside vegetative corridor of native species along restored or permanently diverted intermittent and perennial (but not ephemeral) streams. Similar to the reforestation and revegetation requirements, the additional biomass along streams prescribed by the streamside vegetative corridors increases the terrestrial carbon sequestration potential of the mine landscape.

4.2.4.3 Analytic Methods for Estimating Impacts to Air Quality, Greenhouse Gas Emissions, and Climate Change

To evaluate the potential effects of the Action Alternatives on air quality, greenhouse gas emissions, and climate change, this analysis weighs the multiple relevant effects of implementing the Action Alternative elements. Specifically, it is important to consider the potential direction and magnitude of the following potential effects described above:

1) Changes in emissions from equipment and vehicles due to changes in haulage activities and in overall coal production levels;
2) Effects of reforestation and revegetation requirements on wind transport of materials;
3) Effects of reforestation and revegetation on terrestrial carbon sequestration;
4) Effects of reduced coal production on toxic emissions from blasting and fugitive methane emissions; and
5) Effects of reduced coal production and combustion on greenhouse gas emissions.

The focus of the quantitative analysis in this section is on the effect of the Action Alternatives on greenhouse gas emissions, in particular CO_2 emissions from coal and natural gas combustion, and methane emissions from coal and natural gas production activities. The assessment of impacts in Section 4.2.4.4 additionally includes a qualitative assessment of potential effects on vehicle and equipment emissions, wind transport of materials, terrestrial carbon sequestration, and emissions from blasting. This analysis is based on careful consideration of information on the potential direction and magnitude of these effects. The quantitative information related to benefits of greenhouse gas emissions reductions from coal combustion is only one factor in determining the net effect of the Action Alternatives on air quality. Of note, the monetized benefits of greenhouse gas emission reductions reflect avoided worldwide damages as greenhouses gases contribute to climate change and related damages globally.

As noted, the most significant quantified effect of the Action Alternatives on greenhouse gas emissions is associated with reductions in CO_2 emissions from coal combustion. Approximately 30 percent of total U.S. CO_2 emissions, 1.8 billion short tons, were generated by coal combustion in 2014 (U.S. EPA, 2016b). With respect to coal mining activities (as opposed to coal combustion), however, methane is the predominant greenhouse gas emissions source, accounting for the significant majority of greenhouse gas emissions. In 2013, the EPA's Greenhouse Gas Reporting Program (GHGRP) estimated that reporting mines produced 41.3 million tons of CO_2 equivalents ($MMtCO_2e$) of methane, compared to 0.2 $MMtCO_2e$ of CO_2 and less than 0.05 $MMtCO_2e$ of nitrous oxide (U.S. EPA, 2014h).

4.2.4.3.1 Method for Estimating Benefits of Reductions in Greenhouse Gas Emissions

As noted above, the quantified changes in emissions are not associated with changes in the management of coal mining operations as prescribed by the Action Alternatives. They are instead associated with the overall reduction in coal mining activity due to the increased cost of coal production. Consistent with the Council on Environmental Quality (CEQ) guidance to quantify both the direct and indirect GHG emissions from the proposed action, this analysis considers overall changes in coal combustion nationally due to implementation of the Action Alternatives. This analysis of greenhouse gas emissions reductions applies to the following steps.

4.2.4.3.2 CO_2 Emissions Reductions

1) **Quantify changes in CO_2 emissions from electricity sector associated with the Action Alternatives, as well as the No Action Alternative in year 2020.** The EVA model applied in the coal production analysis described in Section 4.1 additionally projects the associated CO_2 emissions from the electric power sector for the contiguous U.S. (the lower 48 states, exclusive of Washington, D.C.) for each year of the analysis. These estimates are inclusive of emissions from

coal combustion, as well as other sources, including natural gas combustion and renewable sources.

2) **Subtract CO_2 emissions for each Action Alternative from CO_2 emissions for the No Action Alternative to determine the net reduction CO_2 emissions.** For each Action Alternative, this subtraction reflects the change in CO_2 emissions reflecting the combined effect of reductions in emissions from coal combustion and increased emissions from natural gas combustion and other substitute sources of electricity production. The EVA model finds the lost generation from coal is made up for with increased natural gas fired plants. Given the relatively minor reduction in energy production from coal, the EVA model does not find an increase in generation from renewable sources nor does it project a net reduction in demand for energy.

3) **Monetize the reduction in CO_2 emissions applying well-accepted estimates of the social cost of carbon dioxide (SC-CO_2).** Reduced greenhouse gas emissions contribute to climate stabilization. To the extent that the Action Alternatives influence emissions, they also influence a variety of socioeconomic outcomes related to climate change, including agricultural productivity, human health, flooding damages, and various ecosystem services. The SC-CO_2 is applied in this analysis to estimate the benefits associated with CO_2 reductions. The SC-CO_2 is the monetized value of future worldwide damages associated with a one-ton increase in CO_2 emissions in a particular year discounted to the present. Alternatively, it represents the benefit of a one-ton CO_2 reduction. The Interagency Working Group (IWG) on the Social Cost of Greenhouse Gases issued guidelines to help agencies assess the climate change-related benefits of reducing carbon emissions and integrate these estimates into their assessments of regulatory impacts (IWG, 2016a). The Interagency guidance provides a social cost of carbon (SC-CO_2) dollar value based on the average of three specific models. The monetized climate-related benefits resulting from a reduction in CO_2 emissions is calculated by multiplying the estimated decrease in CO_2 emissions in a particular year by the SC-CO_2 value appropriate for that year and discounting to determine the present value in the analysis year.[34]

4.2.4.3.3 CH4 Emissions Reductions

The quantified change in methane emissions in this analysis accounts for fugitive emissions from field production of coal (associated with reduced production) and natural gas (associated with increased production), as well as emissions from vehicle and equipment use, and transportation and storage.

1) **Estimate the reduction in coal production associated with each of the Action Alternatives.** As summarized in Section 4.1, the EVA model reports coal production levels under the baseline No Action Alternative and each of the Action Alternatives. The reduction in coal production is the difference between production under the Baseline and under the Action Alternatives

2) **Estimate reduction in energy generation from coal (in gigawatt-hours (Gwh)).** This step relies on estimates of total Gwh of energy generated from coal production nationally divided by

[34] Alternatively, the SC-CO_2 can be used to estimate the impacts of emission increases. The methodology is the same as that to estimate benefits of emission reductions—multiplying the SC-CO_2 estimates for a specific year by emission changes in that same year—but represent the value of damages or costs associated with the increase in emissions rather than the benefits of avoiding those damages through reductions.

the amount of coal burned to produce that energy to determine an average emissions factor of Gwh/million tons of coal produced. This is then multiplied by the reduction in coal production (Step 4) for each alternative to calculate the reduction in Gwh of energy generated from coal.

3) **Calculate change in methane emissions from coal.** This analysis applies an emissions factor calculated based on a well-accepted and publicly available source of emissions information, the U.S. EPA April 2016 *Inventory of U.S. Greenhouse Gas Emissions and Sinks,* to estimate the change in methane emissions from reductions in coal production for the purposes of electric power generation (U.S. EPA, 2016b). The emissions factor is approximately 11.5 tons of CO_2 equivalents of methane per Gwh of energy production from coal. Multiplying this by the reduction in Gwh from coal energy calculates the reduction in methane emissions from coal. The methane emissions reductions reflect fugitive emissions from field production of coal, emissions from vehicle and equipment use, and transportation and storage.

4) **Estimate increase in energy generation from natural gas.** As identified by the EVA model, the total reduction in Gwh from coal is made up via additional production from natural gas.

5) **Calculate change in methane emissions from natural gas.** Similar to the coal methane emissions analysis, this step applies an emissions factor calculated based on the U.S. EPA, April 2016 *Inventory of U.S. Greenhouse Gas Emissions and Sinks* to estimate the change in methane emissions from an increase in energy generation from natural gas (U.S. EPA, 2016). The emissions factor is approximately 17.9 tons of CO_2 equivalents of methane per Gwh of energy production from natural gas. Multiplying this by the increase in Gwh from natural gas energy calculates the increase in methane emissions from natural gas. Again, the methane emissions increases here reflect fugitive emissions from field production of natural gas, emissions from vehicle and equipment use, and transportation and storage.

6) **Estimate net effect on methane emission.** The net effect on methane emissions takes into account the reduction from coal and the increase from natural gas. Because the emissions factor for natural gas methane emissions is greater, the net effect of the Action Alternatives is an increase in methane emissions.

7) **Monetize the change in CH_4 emissions applying estimates of the social cost of methane.** Similar to the monetization of the benefits from CO_2 emission reductions analysis described above, this step relies on valuing the climate damages associated with the CH_4 emissions increase with IWG recommended estimates of the social cost of methane (IWG 2016b), which similarly reflects climate change-related damages per additional unit of methane in the atmosphere. The monetized climate damages related to a specific proposed action is calculated by multiplying the estimated increase in CH_4 in emissions in a particular year by the social cost of methane value appropriate for that year and discounting to estimate the present value in the analysis year.

The results of this analysis are included in Table 4.2-30 and 4.2-31.

4.2.4.4 Assessment of Impacts to Air Quality, Greenhouse Gas Emissions, and Climate Change

The assessment of overall impacts to air quality, greenhouse gas emissions, and climate change considers the magnitude of the factors described in Table 4.2-29, as well as their combined effect under each Action Alternative.

Table 4.2-29. Adverse and Beneficial Effects of the Action Alternatives on Air Quality, Greenhouse Gas Emissions, and Climate Change

Factor	Potential Adverse Impacts of the Action Alternatives	Potential Beneficial Impacts of the Action Alternatives
Greenhouse Gas Emissions	Increased emissions of methane related to substitute energy production from natural gas Increased emissions (CO_2, N_2O) due to increased haulage.	Decreased CO_2 emissions associated with reduced coal combustion Decreased levels of CO_2 in the atmosphere due to increased terrestrial carbon sequestration potential of landscape given reforestation requirements.
Vehicle and Equipment Emissions	Increased emissions due to increased haulage.	Decreased emissions due to overall reductions in coal production levels.
Wind Transport of Dust	Increased due to increased haulage.	Decreased due to revegetation and reforestation requirements. Decreased due to overall reductions in coal production levels.
Release of Toxic Pollutants from Blasting	None.	Decreased due to overall reductions in coal production levels.

Notes: This table references the national level adverse and beneficial effects of these factors. There are limited differences from these findings at the regional scale under some Action Alternatives.

4.2.4.4.1 Potential Impacts on Vehicle and Equipment Emissions

The Action Alternatives may influence the emissions levels of criteria pollutants and greenhouse gases from vehicles and equipment (e.g., criteria pollutants include carbon monoxide, sulfur dioxide, nitrogen oxides, VOCs, and particulate matter (PM_{10} and $PM_{2.5}$), greenhouse gases including CO_2 and nitrous oxide) both positively and negatively. As reduced coal mining activity levels are expected under the Action Alternatives (excluding Alternative 9), it is possible that vehicle and equipment use and associated air pollution would likewise be reduced. On the other hand, some elements of the Action Alternatives, such as requirements to filling streams with excess spoil, may increase the use of equipment and vehicles for hauling materials on the mine site, which would increase related emissions. While information limitations preclude quantifying this potential effect, the combined effect on equipment and vehicle emissions is most likely a minor, if any, difference from the No Action Alternative. The changes in levels of coal production are relatively minor across the Action Alternatives (each Action Alternative results in an average annual decrease of less than 0.5 percent of coal production, relative to projected baseline production). Furthermore, while the engineering analysis determined that placement of excess spoil outside of streams may potentially require additional travel for haulage, it is not anticipated to result in a substantial additional vehicle miles traveled and therefore not account for a substantial increase in associated emissions.

4.2.4.4.2 Potential Impacts on Particulate Matter and Wind Transport of Dust

Reforestation and vegetation requirements of the Action Alternatives may reduce the extent to which materials are exposed to wind erosion, reducing particulate matter concentrations in air. This benefit is likely a shorter term benefit, as under the No Action Alternative most postmining landscapes would eventually return to vegetated states. Reduced wind transport of dust is expected to be a relatively minor benefit in most regions, and a potentially greater benefit in Appalachia, which has a greater premining forest land cover profile, as described in Section 4.2.2. In addition, Alternatives 2, 4, and 7 prohibit burning of all vegetation or other organic materials, whereas Alternatives 3, 5, and 8 (Preferred) prohibit burning of aboveground debris from native vegetation. Reductions in the extent of burning that occurs on the mine site reduces the amount of airborne particulate matter, thus benefitting air quality at a local level.

4.2.4.4.3 Potential Impacts on Release of Toxic Pollutants from Blasting

None of the rule elements directly reduces or changes blasting practices. The overall reductions in coal production associated with the implementation of the Action Alternatives may, however, reduce overall levels of blasting activity. This benefit is likely negligible, however, as the reductions in coal production levels are modest and it is unclear whether these reductions would be associated with a reduced need for blasting.

4.2.4.4.4 Potential Impacts on Greenhouse Gas Emissions/Levels

In 2016, the Council on Environmental Quality (CEQ) released Final Guidance for Federal Departments and Agencies on Consideration of Greenhouse Gas Emissions and the Effects of Climate Change in National Environmental Policy Act Reviews. This section addresses key topics and concepts recommended in the CEQ guidance, as they relate to the Action Alternatives and their effect on greenhouse gas emissions and climate change. The findings draw on the conclusions discussed throughout this section.

The net impact of the Action Alternatives on emissions of greenhouse gases is difficult to predict with precision. As noted above, hauling vehicles, other heavy equipment, and blasting emit greenhouse gases such as CO_2, nitrous oxides, and methane. While the Action Alternatives are expected to have a Negligible effect on vehicle emissions and blasting, as described above, the Action Alternatives may affect greenhouse gas emissions in other ways. Predominantly, a reduction in coal combustion associated with the decreased coal mining activity generates a reduction in combustion-related CO_2 emissions. Second, the substitute energy generation from natural gas results in a net increase in methane emissions. Finally, reforestation and streamside vegetative corridor requirements of the Action Alternatives increase the terrestrial carbon sequestration potential of the landscape, reducing the level of greenhouse gases in the atmosphere. In these ways, the Action Alternatives (except Alternative 9) may result in climate change benefits due to net reduction in GHGs.

4.2.4.4.5 Estimated Changes in Greenhouse Gas Emissions

Table 4.2-30 summarizes the results of the greenhouse gas emissions analysis in terms of the benefit of the Action Alternatives in reducing greenhouse gases emitted into the atmosphere. The effect varies across the timeframe of the analysis based on the variation in impacts on coal production. Table 4.2-30 presents the results for the first year of the analysis (2020). This analysis does not quantify changes in emissions across the full timeframe of the analysis. This is because of the significant uncertainty with respect to how GHG emissions may change in the baseline due to emerging regulations, voluntary programs, and industry initiatives. Instead, this analysis presents the results for a single year to demonstrate the magnitude of the potential beneficial effect. Overall, the Action Alternatives reduce CO_2 emissions from combustion and slightly increase methane emissions as production of the substitute natural gas generates greater methane emissions than coal production. However, the methane emissions increases (expressed as carbon dioxide equivalents for comparison purposes) are minor compared with the CO_2 emissions reductions.

Table 4.2-30. Potential Effects of Action Alternatives on Greenhouse Gas Emissions

Alternative	Change in CO_2 Emissions in 2020 (short tons)	Change in CH_4 Emissions in 2020 (short tons of CO_2 equivalents)
2	(4,900,000)	28,000
3	(2,900,000)	20,000
4	(2,600,000)	18,000
5	(890,000)	8,600
6	(2,000,000)	14,000
7	(2,700,000)	18,000
8 (Preferred)	(2,600,000)	17,000
9	0	0

Notes:
Estimates are rounded to two significant digits and therefore may not sum to totals reported due to rounding.
Parenthesis indicate negative numbers.
The negative numbers for CO_2 represent a reduction in CO_2 and the positive numbers for methane represent an increase in methane emissions under the Action Alternatives.
This analysis relies on emissions estimates from the U.S. EPA Greenhouse Gas Inventory, which reports CH_4 emissions from coal and natural gas production in terms of CO_2 equivalents applying a global warming potential (GWP) factor for methane of 25.

Sources:
CO_2 emissions estimates from Energy Ventures Analysis (EVA) Analysis, September 2016.
CH_4 emissions rate information derived from: U.S. EPA, April 2016. Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990-2014. Tables 3-29 and 3-46.

While this table reflects the most significant sources of greenhouse gas emissions associated with coal production (and substitute natural gas production), multiple technological and economic factors complicate a precise accounting of the net effects of the Action Alternatives on greenhouse gas emissions from mining and fuel combustion:

- Data are not available to quantify the magnitude or direction (positive or negative) of all emissions-related changes at a given mine site. Elements of the Alternatives may generate counteracting effects for the coal that continues to be produced (e.g., while reductions in combustion may decrease emissions, increased use of vehicles and other equipment use may increase them). However, these types of emissions effects are likely to be minor when compared with the quantified changes in emissions from combustion. Furthermore, rule elements related to reforestation and revegetation may increase the terrestrial carbon sequestration potential of the postmining landscape, additionally reducing the negative effects of climate change.

- Significant uncertainty exists related to the regulation and management of greenhouse gas emissions from fossil fuel production. For example, to the extent that there is an increase in the practice of capture and reuse of greenhouse gases as part of natural gas or coal production, our baseline estimates of emissions could lead to an underestimate or overestimate of the climate benefits of the Action Alternatives.
- The analysis finds that foregone coal-generated energy is primarily substituted with natural gas (the level of substitute with renewables is insignificant). To the extent there are unexpected differences in the supply of natural gas over the timeframe of the analysis, the market could respond by substituting other fuels for coal and that overall change in coal production could be greater or lower.
- Data describing CO_2 (associated with coal mining as opposed to coal combustion) and nitrous oxide emissions are more limited than for methane; thus, this analysis is not able to quantify how emissions of these greenhouses gases would change in response to the Action Alternatives. While the GHGRP requires underground mines that emit more than 36.5 MMCF of natural gas annually to report CO_2 and nitrous oxide emissions, such a small percentage of mines are required to report that these data do not support generalized estimates of emissions factors. However, the available information from the GHGRP indicates that methane accounts for the vast majority of greenhouse gas emissions from coal mining. Specifically, in 2013, as noted above, reporting mines produced 41.3 MMtCO_2e of methane, compared to 0.2 MMtCO_2e of CO_2 and less than 0.05 MMtCO_2e of nitrous oxide. Given the relatively low emissions levels of these other pollutants, and assuming that emission trends are similar for surface mines and smaller underground mines (smaller than those reporting emissions), any changes in CO_2 and nitrous oxide emissions resulting from the Action Alternatives are likely to be Negligible.

For these reasons, a specific reduction in greenhouse gas emissions resulting from decreased coal production is difficult to predict with confidence. The results of this analysis, however, provide an order-of-magnitude perspective on the potential benefit.

4.2.4.4.6 Potential Effects on Terrestrial Carbon Sequestration

Each of the Action Alternatives (excluding Alternative 9) specifies additional reforestation/ revegetation and streamside vegetative corridor requirements. These changes expedite the return of postmining land to a native forest ecosystem and maintain streamside vegetative. While a primary objective of these requirements is reduction of erosion and sedimentation, trees and other vegetation remove CO_2 from the atmosphere and transform the carbon into biomass. This type of terrestrial carbon sequestration is enhanced by improved and expedited reforestation. Section 4.2.2 evaluates the benefits of the Action Alternative in terms of preserved (forest that is preserved from cutting for mining) and improved (better forest management practices) forest land. The evaluation of the terrestrial carbon sequestration benefits in this section accordingly reference the reforestation analysis described in Section 4.2.2, as increased forest results in increased terrestrial carbon sequestration potential.

4.2.4.4.7 Social Cost of Carbon

The monetized climate benefits of the Action Alternatives described in Table 4.2-31 are calculated by applying the net changes in emissions of each gas (CO_2 and CH_4), described in Table 4.2-30, to the estimates of the social cost of carbon and the social cost of methane, respectively, recommended by the

IWG (IWG 2016a, 2016b). The table describes the impacts within the first year of the analysis due to uncertainty regarding emissions profiles of the electricity sector in the future under the No Action and Action Alternatives (e.g., due to emerging regulations and voluntary programs).

The IWG guidance (IWG 2016a, IWG 2016b) relies on the use of three integrated assessment models (IAMs), three discount rates, and four scenarios to represent distributions for the global social cost of GHGs. Consistent with this guidance, Table 4.2-31b presents the results of the analysis for four valuation scenarios: three values are based on the average social cost of GHGs (i.e., CO_2 and CH_4) across models and socio-economic-emissions scenarios with discount rate assumptions of 2.5 percent, 3 percent, and 5 percent. The fourth valuation scenario reflects "higher-than-expected" economic impacts from climate change discounted at the 3 percent rate (the 95th percentile scenario). Due to uncertainty regarding the impacts of climate change and the social cost of GHGs, the IWG emphasizes the importance of presenting all of the scenarios in an analysis of changes in GHG emissions. The 3 percent discount rate average scenario represents the central estimate.

It is important to note that the social cost of greenhouse gas estimates applied in this analysis reflect the avoided worldwide damages from climate change. The IWG determined that consideration of a global measure of benefits from reducing U.S. GHG emissions is appropriate because anthropogenic climate change involves a global externality: emissions of most greenhouse gases contribute to damages around the world even when they are emitted in the United States, and conversely, greenhouse gases emitted elsewhere contribute to damages in the United States. Consequently, to address the global nature of the problem, estimates of the social cost of greenhouse gases must incorporate the full (global) damages caused by emissions. In addition, climate change presents a problem that the United States alone cannot solve. Other countries will also need to take action to reduce GHG emissions if significant changes in the global climate are to be avoided. Furthermore, adverse impacts on other countries can have spillover effects on the United States, particularly in the areas of national security, international trade, public health, and humanitarian concerns. Thus, the IWG concluded that a global measure of the benefits from reducing U.S. emissions is preferable.

Table 4.2-31a. Estimated Benefits of Greenhouse Gas Emissions Changes Resulting from the Action Alternatives

Alternative	Change in Worldwide Damages due to Reduction in CO_2 Emissions in 2020 (2014$, 3% discount rate)	Change in Worldwide Damages due to Increase in CH_4 Emissions in 2020 (2014$, 3% discount rate)
2	($210,000,000)	$2,400,000
3	($130,000,000)	$1,700,000
4	($110,000,000)	$1,500,000
5	($38,000,000)	$740,000
6	($85,000,000)	$1,200,000
7	($120,000,000)	$1,600,000
8 (Preferred)	($110,000,000)	$1,500,000
9	$0	$0

Notes: Estimates are rounded to two significant digits and therefore may not sum to totals reported due to rounding. Parenthesis indicate negative numbers.
The negative values for CO_2 emissions-related damage reductions reflect a benefit (i.e., a reduction in climate-related damages) whereas the positive values for increased CH_4 emissions represent a net cost (i.e., an increase in climate related damages).

4.2.4.5 Summary of Effects

The overall finding with respect to the impacts of the Action Alternatives on air quality, GHG emissions and climate change are based on both the qualitative and quantitative findings discussed above. While none of the Action Alternatives explicitly targets air quality resources, implementation of the elements of the Action Alternatives (except Alternative 9) have beneficial effects on air quality, greenhouse gas emissions, and climate change, in particular by reducing the overall level of coal production. In addition, the Action Alternatives (except Alternative 9) increase terrestrial carbon sequestration potential of the landscape due to reforestation and streamside vegetative corridor requirements of Alternatives. The Alternatives may also increase methane emissions from natural gas, and increase the use of equipment and vehicles to haul materials, and therefore increase other emissions from these sources. While data are not available to quantify with precision these potential effects of the Action Alternatives on emissions or ambient air quality, the net effects to air quality, greenhouse gas emissions, and climate change are Beneficial (except under Alternative 9).

4.2.4.5.1 Alternative 1 (No Action Alternative)

Under the No Action Alternative, no further regulations or corrective measures in addition to those already in place would be implemented. Therefore, ongoing trends in air quality, greenhouse gas emission, and climate change would continue. The annual quantity of coal demanded and associated production is anticipated to be approximately 10 percent lower in 2040 than in 2020, even without implementation of the Alternatives (i.e., under the No Action Alternative). This reduction in production would reduce adverse impacts on air quality and climate change associated with coal mining activities under the No Action Alternative.

A multitude of other past, present, and reasonably foreseeable future actions affect air quality and greenhouse gas emissions. Coal mining generally negatively affects air quality due to air emissions emanating from vehicle engines or explosives detonation, erosion and wind transport of dust, and release of fugitive methane emissions during mining activities. In a national-scope rulemaking such as the SPR, however, numerous other regulatory and non-regulatory actions influence air quality. While some air quality issues are local (toxic releases during blasting activities), others, such as greenhouse gas emissions and their relationship to climate change, have implications at the global scale. Air pollutant emissions are generally regulated and managed at both national and local scales, to minimize the effects of coal mining activity on air quality and global climate change. The effects of coal mining and coal combustion on air pollutant emissions are primarily regulated under the Clean Air Act; additionally, performance standards targeting reducing toxic emissions from blasting is managed under section 515 of SMCRA (30 U.S.C. §1265). Furthermore, permit programs for stationary sources, including federal requirements and state variations on those requirements, affect emissions of a range of pollutants. Regulations are also emerging to address limiting carbon emissions from power plants. Additional programs focused on promoting the recovery and use of coal mine methane may further reduce mining-related air pollutant emissions. On the other hand, continued population and economic trends will greatly affect air quality in any given region. Increased economic growth, population growth, expansion of road and highway systems, residential and commercial construction, and numerous other factors will affect air quality outcomes. A comprehensive accounting of factors affecting air quality in the coal regions under the No Action Alternative is beyond the scope of this analysis.

4.2.4.5.2 Alternative 2

The two key considerations for all Action Alternatives are effects of the Alternative on greenhouse gas emissions and on terrestrial carbon sequestration. Alternative 2 affects both emissions and terrestrial carbon sequestration to the greatest extent as it generates the greatest reduction in coal production and has the most significant reforestation and streamside vegetative corridor requirements.

4.2.4.5.3 Alternative 3

Alternative 3 will have a beneficial effect on air quality and climate change by reducing greenhouse gas emissions commensurate with the reduction in coal production projected for this Alternative.

4.2.4.5.4 Alternative 4

Alternative 4 will have a beneficial effect on air quality and climate change by reducing greenhouse gas emissions commensurate with the reduction in coal production projected for this Alternative.

4.2.4.5.5 Alternative 5

As explained in Chapter 2, Alternative 5 has little effect on any coal region other than the Appalachian Basin. Alternative 5 is projected to reduce coal production, however, as well as improve terrestrial carbon sequestration potential due to reforestation requirements in Appalachia. This Alternative is, therefore, anticipated to have a beneficial effect on air quality and climate change.

4.2.4.5.6 Alternative 6

Alternative 6 does not incorporate the same reforestation and revegetation requirements as other Action Alternatives and therefore is unlikely to generate terrestrial carbon sequestration benefits. The key effect of Alternative 6 on air quality and climate change is the reduction in GHG emissions from coal combustion. As with the other Action Alternatives, Alternative 6 is projected to have a beneficial effect on air quality and climate change.

4.2.4.5.7 Alternative 7

Alternative 7 applies to a more limited number of mine sites (i.e., those sites where enhanced permitting requirements apply). Alternative 7 will have a beneficial effect on air quality and climate change by reducing greenhouse gas emissions commensurate with the reduction in coal production projected for this Alternative.

4.2.4.5.8 Alternative 8 (Preferred)

Alternative 8 (Preferred) is similar to Alternatives 3 and 4 in terms of the potential terrestrial carbon sequestration benefits, although the estimate of preserved forest acres is slightly lower under Alternative 8 (Preferred) given the slightly lesser decrease in coal production. Alternative 8 is also similar to Alternatives 3 and 4 with respect to the projected impact on coal production, and therefore on GHG emissions. The overall effect of Alternative 8 is beneficial with respect to air quality and climate change.

4.2.4.5.9 Alternative 9

Alternative 9 would require the repromulgation of the currently vacated 2008 Stream Buffer Zone rule. The model mines analysis indicates that the impacts of Alternative 9 would not differ significantly from those of the No Action Alternative because the Clean Water Act requirements and policies discussed in the Regulatory Impact Analysis for this rulemaking and the state AOC and excess spoil policies identified in Section 4.2.3.1 of this FEIS have effectively achieved implementation of this Alternative in Central Appalachia, which is the region in which the 2008 Stream Buffer Zone rule would have had its greatest impact if it had remained in effect. Therefore, if repromulgated, Alternative 9 would now have Negligible effects on air quality, greenhouse gas emission, and climate change.

4.2.4.6 Potential Minimization and Mitigation Measures

While the overall effect of the Action Alternatives on air quality and climate change is beneficial, the Action Alternatives have some adverse effects. In particular, a slight increase on reliance on natural gas for energy production due to reductions in coal production results in a net increase in methane emissions. Increase use of methane capture and reuse may reduce this adverse effect. However, the net effect of the Action Alternatives on total greenhouse gas emissions is positive; thus, increased recovery and reuse of methane emissions would result in even greater climate stabilization benefits of the Alternatives.

4.3 Social and Economic Resources

4.3.1 Socioeconomic Conditions

This section evaluates the potential impacts of the Action Alternatives on socioeconomic characteristics of the seven coal regions. Section 4.1 describes impacts specifically to the coal mining industry, while this section focuses on the effects of the Alternatives on the broader regional socioeconomic environment. This section:

- Describes the existing environment with respect to socioeconomic resources. For more details on the socioeconomic characteristics of the seven coal regions please refer to Section 3.14;
- Describes the potential effects of the Action Alternatives on employment, regional income, property value, tax revenues, and quality of life;
- Details the analysis conducted to determine the potential impacts to these resources under each Action Alternative and results of these analyses;
- Describes the uncertainty and limitations inherent in the analyses; and
- Describes potential minimization and mitigation measures that could be taken to offset potential adverse impacts.

4.3.1.1 Effects of the Current Environment (the No Action Alternative)

Section 3.14 characterizes the socioeconomic resources in each coal region, including demographics, employment, income, property values, tax revenues, and the quality of life. This section briefly discusses this information in the context of the No Action Alternative.

4.3.1.1.1 Demographics

None of the Action Alternatives are expected to produce economic or social impacts on a scale large enough to trigger demographic shifts on a regional basis, such as increasing the relative percentage of any age group.

4.3.1.1.2 Employment and Income

As noted in Chapter 3, coal mining accounts for 0.1 percent of national employment and 0.1 percent of national income. Coal mining-related employment is significantly higher in the Appalachian Basin than in the other coal regions. The general trends in coal market employment and income are anticipated to follow the expected trends in coal production between 2020 and 2040. As described in Section 4.1, total coal production is anticipated to decline over the study period, with annual production falling from 1.1 billion tons (1,106 million tons) in 2020 to 917 million tons in 2040 (a reduction of 162 million tons of coal). The decline in the Colorado Plateau is expected to be about 26 percent of its annual coal production in 2020. In the Appalachian Basin, the change in coal production represents 18 percent of 2020 coal production. In the Northern Rocky Mountains and Great Plains region, the expected decline amounts to about 15 percent of 2020 coal production. Declines in the Illinois Basin and the Western

Interior are 10 and seven percent of 2020 production, respectively. Last, the declines expected in the Gulf Coast and the Northwest both represent less than one percent of 2020 production in their respective regions.

4.3.1.1.3 Tax Revenues

As noted in Chapter 3, policies on taxing the coal mining industry vary from state to state. Many states levy a direct severance tax on extracted minerals. Severance taxes in some states are levied in the form of a percent of the value of the resources removed or sold and in other states as a per-ton fee. Severance taxes collected would be expected to follow a trend that is generally consistent with the future volume of coal produced under the No Action Alternative, as described above.

4.3.1.1.4 Property Values

Mining activities may suppress the value of surrounding properties through noise, aesthetic disturbance, and impacts to air and water quality under the No Action Alternative. For example, the presence of coal dust attributed to nearby coal mining activity has been shown to adversely affect property value in parts of Appalachia (Stockman, 2003). As coal production declines over time under the No Action Alternative, the associated water quality, air quality, and landscape aesthetic improvements may benefit nearby property values. In contrast, to the extent that employment opportunities are reduced due to reductions in coal mining activities under the No Action Alternative, demand for living in coal mining-dependent communities may decrease, which may reduce the value of residential properties in those communities under the No Action Alternative.

4.3.1.1.5 Quality of Life

Coal mining plays an important role in the culture and history of certain regions within the U.S. The industry has played a crucial role in the development and support of communities across the U.S. and often provides the nexus for social networks within these communities. As coal mining declines over time, the social fabric of particular communities may therefore be negatively affected. The quality of life in coal mining communities is also dependent on a reliable employment source. Where coal mining is a key employment opportunity, quality of life may be negatively affected by reductions in mining activity levels, depending on the level of alternative emerging industries and re-employment opportunities.

4.3.1.2 Action Alternatives and Potential Effects on Socioeconomic Conditions

This section focuses on the effects of the Alternatives on regional employment, regional income, property values, tax revenues, and the quality of life in coal-producing regions.

4.3.1.2.1 Employment

Forecast shifts in the geographic distribution of coal production, the manner in which coal is produced (e.g., surface versus underground), and the total quantity of coal produced, are expected to lead to changes in regional coal industry employment, even absent the implementation of the Action Alternatives. This section considers the potential for the Action Alternatives to affect employment in the coal mining industry (i.e., result in direct employment impacts), as well as employment in the broader regional economy (i.e., result in indirect and induced employment impacts to related economic sectors). The Action Alternatives (excluding Alternative 9) have the potential to result in both adverse as well as beneficial effects on employment, varying by industry and region. Employment in the coal mining industry is expected to change as a result of several factors. The applicability of these factors varies by region. For example, a change in the costs of coal production across regions would shift the regional distribution of coal production or may decrease coal production overall. In these cases, regional reductions in mining employment or an overall decrease in mining-related job opportunities will occur. Individual coal regions may experience either an increase or decrease in mining-related employment, depending on how production levels shift between coal regions. All else equal, if Action Alternatives led to a shift from surface mining to underground mining, the number of mining jobs would increase as underground mining is generally more labor-intensive than surface mining.

Certain elements of the Action Alternatives may also increase employment demand within or, in some cases, outside of the mining sector through the introduction of compliance measures. First, some rule elements included under the Action Alternatives may increase employment demand for conducting additional environmental analysis, data collection, or sampling (Baseline Data Collection and Analysis; Monitoring During Mining and Reclamation; Mining Through Streams). Other rule elements may also require labor-intensive field practices (Activities In or Near Streams; Surface Configuration; Revegetation, Topsoil Management, and Reforestation; Wildlife Protection and Enhancement). The extent to which these elements would affect employment demand varies by Action Alternative, both because of differences in the scope of the elements and in the applicability of the elements under each Action Alternative. For example, under Alternatives 2, 3, 4, and 8 (Preferred), the rule elements defined for each Alternative apply to all mining activities, whereas under Alternatives 5, 6, and 7, the applicability of rule elements is more limited.[35] Alternative 9 is not expected to affect employment.

In addition to the direct employment effects within the mining industry, a change in the regional distribution of coal production may also affect employment in industries that provide goods and services to the coal industry or that otherwise rely on coal mining. To the extent that coal production decreases in a particular region, employment in these secondary industries may also be reduced. In contrast, employment in other energy sector industries could increase due to a shift toward substitute fuels (e.g., natural gas) to generate electricity. While increased natural gas demand could result in increased regional economic activity, the magnitude and location of these effects are uncertain, and thus are not quantified in this analysis.

The relationship between environmental regulation and employment is a subject debated within the academic literature. As developed in this chapter and as supported by economic theory, environmental regulation can increase production costs, which according to economic theory should raise prices, reduce demand, and ultimately put downward pressure on employment within a given industry. However, compliance with environmental regulation also typically introduces additional labor requirements. Several studies on the relationship between compliance with environmental regulation and employment topic have found that environmental regulation has a slightly positive overall impact, if any, on employment (Berman and Bui, 2001; Morgenstern, et al. 2002; Bezdek, et al. 2008, Belova, et al. 2013).

[35] As described in previous sections, under Alternative 5, the application of element components is limited to mining activities that result in placement of excess spoil outside the mined area or coal refuse disposal in perennial or intermittent streams. For Alternative 6, the application of components is limited to stream buffer zones. Under Alternative 7, the rule elements apply when certain conditions exist that warrant enhanced permitting requirements.

It should be noted, however, that the literature does not specifically address the relationship between environmental regulation and labor demand in extractive industries such as coal mining. Therefore, the precise relationship examined in this analysis has not been examined in available published literature. Subsection 4.3.1.3 quantifies direct employment impacts to the mining industry.

4.3.1.2.2 Income

The income effects of the Action Alternatives are associated with employment effects, as described above, and may be either beneficial or adverse, depending on the Action Alternative and potential for shifts in coal production between regions or mining methods. Regions that experience a decrease in coal production may experience lower employment and associated income in both the mining industry and in industries providing goods and services to mining operations or that otherwise rely on coal mining. Industry implementation-related requirements imposed on mine operations by the Action Alternatives may result in some increased demand for employment. Some additional jobs created by the Action Alternatives may differ in skill requirements from the production-oriented jobs that would be reduced due to decreased coal production. It is not certain whether particular individuals would seek job retraining. Note that Section 507(c) of SMCRA, 30 U.S.C. § 1257(c), establishes the small operator assistance program (SOAP). To the extent that funds are appropriated for that program, this provision of SMCRA authorizes OSMRE to provide small operators with training and financial assistance in preparing certain elements of permit applications. An operator is eligible to receive training and assistance if his or her probable total annual production at all locations will not exceed 300,000 tons. See the above discussion of employment effects for the specific elements of the Action Alternatives that introduce new industry implementation-related work requirements to mine operations. Subsection 4.3.1.3 quantifies direct labor income impacts to the mining industry.

4.3.1.2.3 Tax Revenue

Where implementation of an Action Alternative generates changes in volume of coal mined or in the location of coal mining activity, severance tax revenues as well as other taxes levied by state and/or tribal governments on coal extraction/production may be affected.[36] That is, a decrease in coal production as a result of an Action Alternative would result in collection of less revenue from coal severance and other related taxes in jurisdictions where such a change in production occurs.[37] Depending on the scale of the reductions in coal production, reduced tax collections could have important implications, particularly for local governments. On the other hand, some reductions in tax revenue associated with reduced coal production may also be replaced by new tax revenues collected on the extraction of substitute fuels, such as natural gas. However the locations for extraction of substitute fuels may differ from those of coal production; thus, the increases in taxes collected from natural gas may not be experienced by the communities which lose tax revenues from coal production. These effects would be less pronounced at the state or regional level. A net reduction in tax revenues could affect the level of funding for public services supported by the lost tax revenue. The demand for some public services, such as road maintenance, may also decrease if mining activity decreases. Conversely, the demand for other services,

[36] Severance taxes are taxes levied on non-renewable resources upon extraction.

[37] Some states base their coal severance taxes on the gross value of coal. Therefore, to the extent that production decreases lead to higher coal prices, tax impacts may be mitigated.

such as certain social services, may increase as mining activity decreases. Depending on the severity of the changes in tax collections, reductions in localized tax revenue collection could lead to declining quality of life conditions and ensuing population declines.

Subsection 4.3.1.5 evaluates the potential effects of the Action Alternatives on coal tax revenue in coal-producing states.

4.3.1.2.4 Property Values

As noted above, mining activities may suppress the value of surrounding land through increased noise, aesthetic disturbance, and impacts to air and water quality. To the degree that the Action Alternatives result in benefits to local water quality, forested acreage, and available recreational resources in and around the mine site, property values may be positively impacted.

Water quality improvements in particular may contribute to improved aesthetic conditions, increased recreational opportunities, and real or perceived human health and ecological risk reductions. These benefits may be realized as increases in property values. The economics literature demonstrates that water quality improvements can positively affect nearby property values. For example, properties may benefit from: improved views if the water quality improvements repair visual disamenities in the water (such as abundant algae); greater quality of water-related recreational opportunities; and/or healthier aquatic ecosystem habitats. The majority of the economics literature valuing water quality improvements considers how improvements in water clarity or turbidity affect property values near water bodies (see e.g., Walsh, et al., 2011; Ara, et al., 2006; Kashian, et al., 2006; Krysel, et al., 2003; Gibbs, et al., 2002). However, some studies demonstrate that other water quality characteristics also affect property values, including algal blooms, level of dissolved inorganic nitrogen, and total suspended solids (TSS) (Leggett and Bockstael, 2000; Poor, et al., 2007). Thus, to the extent that Action Alternatives benefit water quality, property values could also benefit.

In addition, to the extent that coal regions experience a reduction in coal mining activity or a shift from surface to underground mining, localized impacts on property value may occur. Some rule elements also may also improve property amenities, such as requiring mining operations to incorporate improvements in the aesthetics of mined land or to improve the quality of the reclaimed land.

In contrast to the potentially beneficial effects, adverse impacts to property values could also occur if the Action Alternative results in decreased coal employment in communities that are particularly dependent on it. The extent to which Action Alternatives would result in changes to property values when compared to the No Action Alternative varies across regions and Action Alternatives. Subsection 4.3.1.4 evaluates the potential effects of the Action Alternatives on property values in coal-producing regions.

4.3.1.2.5 Quality of Life

As noted above, coal mining plays an important role in the culture and history of certain regions within the U.S. The industry has played a crucial role in the development and support of communities across the U.S. and can provide the nexus for social networks within these communities. To people living in areas where coal mining is deeply entrenched within the culture, a reduction in mining activity may represent not only reductions in income but also a loss of identity and culture.

In addition, in areas that rely heavily on coal mining employment, reduced mining activity may affect the livelihood of the community. Individuals and families may rely on the availability of mining jobs to provide income and benefits important to their well-being, such as health insurance. To the extent that impacts of the proposed action are concentrated in a particular community, these communities may experience a reduced quality of life to the extent that the Action Alternatives result in reduced mining activity. In addition, coal companies may have a philanthropic presence in communities; reduced mining could adversely affect these philanthropic activities. Depending on the severity of the observed changes, declining quality of life in coal-dependent communities could lead to population declines in those communities.

Many elements of the Action Alternatives may also offer quality of life benefits. For example, to the extent that implementation of certain elements of the Alternatives result in improved water and air quality, aesthetic benefits, and increased wildlife populations. Regional populations also may benefit from improved conditions and/or opportunities for recreational activities and health benefits (as described in other sections of this Chapter). Subsection 4.3.1.6 discusses the potential effects of the Action Alternatives on quality of life in coal-producing regions.

4.3.1.3 Employment Impact Analysis

4.3.1.3.1 Approach to Employment Analysis

The analysis of employment impacts estimates the effect of the Action Alternatives on employment in each of the coal regions for the 21-year period of study, from 2020 to 2040. For each Action Alternative, two primary factors drive the overall changes in employment: changes in coal production and additional work required to achieve compliance with the new requirements (referred to here as “industry implementation-related” effects on employment).

Direct effects are those brought about by production changes or additional work required by the Alternative. Indirect effects arise from the “ripple” effect of changes in coal production on local industries that provide goods and services to the coal industry. Induced effects arise from changes in household consumption due to changes in employment and associated income in a region. This analysis focuses on measurement of direct effects, though indirect and induced impacts may also occur. In this analysis, direct effects are measured in two categories:

- **Production-related employment effects**: These effects include changes in industry employment demand associated with changes in coal production that are associated with implementation of the Action Alternatives. Except for Alternative 9, where no changes are anticipated relative to the No Action Alternative, coal production-related employment effects associated with the Action Alternatives are generally anticipated to be negative, as overall coal production is expected to decline.
- **Industry Implementation-related employment effects**: These effects are changes in employment demand in the coal mining sector and other affected industries (not including government) that would occur due to proposed new requirements (e.g., additional employment demand needed to meet new landforming requirements on-site). The new requirements would generate additional need for labor and equipment to conduct hauling of materials; landforming; stream restoration and enhancement;

reforestation; information gathering for enhanced permitting; and various administrative activities. Specific requirements vary across the Action Alternatives. In general, these employment effects are positive, as the Action Alternatives, while experienced as a cost to the coal industry, generate demand for local goods and services.

This analysis presents results for each region that show the range of each Action Alternative's potential incremental impacts (over and above what would be expected under the No Action Alternative), given current economic conditions, on these factors in a given year over the timeframe for the analysis.

The Action Alternatives (excluding Alternative 9) may generate indirect and induced effects. However, these are not reported here because of the uncertainty associated with these calculations.

4.3.1.3.2 Labor Intensity

Employment in the coal mining industry would adjust according to shifts in coal production across regions and mine types. The size of the employment impact depends on both the change in coal production and the labor effort required to achieve that production. Table 4.3-1 lists coal production by coal region and mine type in 2015. Regions where coal mining is more labor-intensive would experience a greater employment impact than areas where coal is more easily extracted, given the same shift in coal production. Labor requirements vary widely across regions and mine type. Table 4.3-2 describes average employment in 2015 for both surface and underground mining in the seven coal regions. Table 4.3-3 highlights the variation across regions and mine types in terms of mine operator full-time equivalents (FTE) per million tons of coal produced. These employee numbers are collected by MSHA from "reports by operators of mines for personnel directly engaged in production, cleaning, milling, shipping, development, and maintenance and repair work, including direct supervisory and technical personnel and contract mining services" (MSHA, 2015c). This statistic is reported as the standard measure of coal mine labor productivity, average production per employee per hour, in Table 4.3-4.

Extraction of coal from surface mines in the Appalachian Basin is relatively labor-intensive (i.e., requiring a high level of labor per ton of coal produced). As such, a small change in coal production would lead to a relatively large change in employment in this region. Surface mines in the Colorado Plateau and Northern Rocky Mountains and Great Plains regions require less labor per ton of coal produced; thus, a change in coal production would generate a relatively lower change in mining-related employment. Underground mining generally is more labor-intensive than surface mining. In particular, the Western Interior and Appalachian Basin regions are the most labor-intensive regions for underground coal mining.

Table 4.3-1. Coal Production by Region, 2015 (Million short tons)

Coal Region	Surface	Underground	Total
Appalachian Basin	54.8	167	222
Colorado Plateau	22.5	29.6	52.1
Gulf Coast	41.8	NA	41.8
Illinois Basin	27.5	96.4	124
Northern Rocky Mountains and Great Plains	440	13.6	454

Northwest	1.19	NA	1.19
Western Interior	1.44	0.48	1.62
Total	589	308	897

Source: MSHA. 2015. MSHA Annual Coal Production Data 2015. Provided by OSMRE April 12, 2016.
Note: Estimates may not sum to the totals reported due to rounding.

Table 4.3-2. Average Employment by Coal Region and Mine Type, 2015 (Number of Employees)

Coal Region	Surface	Underground	Total
Appalachian Basin	8,599	25,355	33,954
Colorado Plateau	1,318	2,420	3,738
Gulf Coast	3,230	0	3,230
Illinois Basin	2,148	8,195	10,343
Northern Rocky Mountains and Great Plains	8,804	969	9,773
Northwest	112	0	112
Western Interior	205	147	352
Total	24,416	37,086	61,502

Source: MSHA. 2015. MSHA Annual Coal Production Data 2015. Provided by OSMRE April 12, 2016.
Note: Includes all employees engaged in production, preparation, processing, development, maintenance, repair shop, or yard work at mining operations, including office workers. Excludes preparation plants with fewer than 5,000 employee hours per year, which are not required to provide data.

Table 4.3-3. Employment in Coal Industry per Million Tons of Coal Production, 2015

Coal Region	Surface	Underground
Appalachian Basin	276.3	282.5
Colorado Plateau	76.5	118.4
Gulf Coast	120.8	NA
Illinois Basin	116.9	146.4
Northern Rocky Mountains and Great Plains	31.7	97.5
Northwest	102.8	NA
Western Interior	264.8	372.8

Source: MSHA. 2015. MSHA Annual Coal Production Data 2015. Provided by OSMRE April 12, 2016

Note: This figure is calculated using 2015 estimates of the employment per million tons produced. To be conservative (i.e., more likely to overstate than understate impacts), the average of the least productive mines in each region that comprise at least 25 percent of total production in that region is used.

Table 4.3-4. Worker Productivity (Average Production per Operator Employee Hour) (short tons), 2015

Coal Region	Surface	Underground
Appalachian Basin	1.7	1.7
Colorado Plateau	6.3	4.1
Gulf Coast	4.0	NA
Illinois Basin	4.1	3.3
Northern Rocky Mountains and Great Plains	15.2	4.9
Northwest	4.7	NA
Western Interior	1.8	1.3

Source: MSHA. 2015. MSHA Annual Coal Production Data 2015. Provided by OSMRE April 12, 2016.

Note: Derived from 2015 average workers per million tons of coal production. Assumes a single employee works 2080 hours per year.

4.3.1.4 Results of Employment Impacts Analysis

Estimated employment impacts vary from year to year and across regions and Alternatives. Tables 4.3-5 through 4.3-12 present the average annual impacts and the maximum and minimum annual impacts for each Alternative and region. Alternative 9 is not expected to result in production changes or employment effects and is therefore excluded from this discussion.

Definitions of the metrics presented in the tables are as follows:

- "Average over 21 years" is the average effect of the Alternative over the study period for the analysis on employment.
- "Range in any year" is the minimum and maximum effect on employment in any year in the study period.
- "Production-related employment effects" are calculated as effects associated with changes to coal production that are expected as a result of the Alternative. These are calculated using assumptions related to employment per ton of coal produced. The production-related job losses are associated only with the coal that is not produced because of changes associated the Alternatives.
- The range of effects to Surface Employment represents the minimum and maximum effect in any year in the study period.
- The range of effects to Underground Employment represents the minimum and maximum effect in any year in the study period.
- The range of effects to Surface and Underground Combined employment represents the minimum and maximum impact in any year in the study period when the surface and underground mining effects are considered together. Because the minimum and maximum effects of the Alternative on surface and underground mining do not always occur in the same year, the combined impact is not always equal to the sum of the Surface and Underground ranges.
- **"**Industry implementation-related employment effects" are calculated as effects associated with changes to expenditures on industry implementation-related activities and are calculated using assumptions related to employment demand per dollar spent on compliance. The industry implementation-related job effects are a function of all coal that is produced in any year in each region.

As shown, year to year variation reflects changes in coal production over the study period. In general, as U.S. coal production declines over the time period for the analysis, costs of compliance and associated reductions in production-related employment also decline. In general, regional employment impacts from changes in production are greatest in the Appalachian Basin, Illinois Basin, and Northern Rocky Mountains and Great Plains regions. Industry implementation-related employment impacts occur more evenly across the regions, but are typically largest in the Appalachian and Illinois Basin regions. Forecasted changes in employment demand are both positive and negative. Decreases in expected employment demand appear in parentheses. The range in production-related employment values reported is driven by annual variability in proportions of mining by type (surface versus underground) and in the overall volume of coal produced.

4.3.1.4.1 Production-related Employment Effects

The volume of coal production nationally is expected to decrease under all the Action Alternatives (except Alternative 9), which would reduce employment in the coal industry as well as industries that process mined coal or provide goods and services to mining operations throughout the production process. Affected entities could include coal processing facilities, power plants, mining and construction equipment manufacturers, the coal transportation industry, and a variety of other local businesses located near mining operations in coal-producing regions. Decreased coal production would lower demand for these goods and services provided, which, in turn, decreases income and employment in these supporting industries. As stated above, to the extent that coal production is replaced by extraction of another domestic fuel supply, employment impacts could be mitigated at the regional or national level by increasing employment in industries that extract substitute fuels, such as natural gas.

As shown in Tables 4.3-5 through 4.3-12, production-related employment impacts for mine operations are greatest in Alternative 2, with a reduction of 270 full time equivalents (FTEs) per year on average. Alternatives 3 and 7 are expected to reduce FTEs by approximately 170 per year on average. Alternatives 4, 5, and 8 (Preferred) would cause smaller reductions in FTEs by approximately 150, 100, and 120 FTEs per year on average, respectively. Except for Alternative 9, Alternative 6 is expected to have the smallest reduction in FTEs with approximately 90 FTEs lost per year on average.

4.3.1.4.2 Industry implementation-related employment effects

As discussed in Section 4.3.1.2, increases in employment demand due to work requirements imposed on mining operations by the Action Alternatives could occur. These additional work requirements include performing inspections, conducting biological surveys, constructing digital elevation models, and other tasks that require specific expertise in these fields. Individual workers that are currently involved in coal production may require additional training to perform and benefit from these new work requirements. Other increased work requirements associated with elements contained in the Action Alternatives are expected to require similar skills as currently used by the industry (e.g., bulldozer operations).

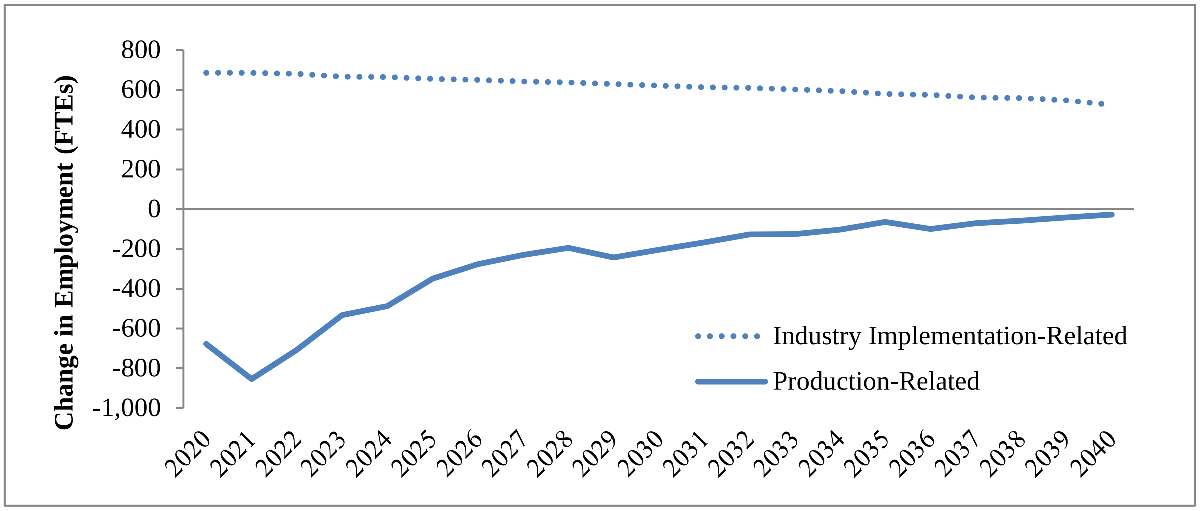
Industry implementation-related employment effects would occur primarily in regions with the largest increases in compliance costs, particularly in the Appalachian and Illinois Basin regions. As shown in Tables 4.3-5 through 4.3-12, impacts to industry implementation-related employment is greatest under Alternative 2 with employment increasing by approximately 620 FTEs per year on average. Alternative 3 has impacts on industry implementation-related employment of 419 FTEs per year on average. Alternatives 5 and 6, which have more limited compliance areas, lead to 193 and 272 FTEs in industry implementation-related employment per year on average, respectively. Under Alternative 5, effects occur in the Appalachian Basin while under Alternative 6 effects are clustered in the Appalachian and Illinois Basin regions. Alternative 7, which also has targeted compliance efforts, leads to 252 FTEs in industry implementation-related employment per year on average. Alternative 8 (Preferred) is expected to have implementation-related employment increase of 280 FTEs per year on average. Alternative 4 has the lowest increase in implementation-related employment with an expected increase of 105 FTEs per year on average.

Table 4.3-5. Estimated Changes in Annual Employment under Alternative 2 Compared to the No Action Alternative, 2020-2040 (FTEs)

Region	Metric	Production-Related Employment Effects[3] Surface[4]	Production-Related Employment Effects Underground[5]	Production-Related Employment Effects Surface and Underground Combined[6]	Industry implementation-related Employment Effects[7]
Appalachian Basin	Average over 21 years: [1]	(100)	(140)	(210)	400
	Range in any year: [2]	(248) - (4)	(447) - (0,017)	(694) - (21)	339 - 439
Colorado Plateau	Average over 21 years:	0	0	0	10
	Range in any year:	0 - 1	0 - 1	(1) - 2	12 - 15
Gulf Coast	Average over 21 years:	(1)	0	(1)	48
	Range in any year:	(8) - 13	0 - 0	(8) - 13	45 - 50
Illinois Basin	Average over 21 years:	(8)	(44)	(52)	110
	Range in any year:	(30) - 0	(130) - 0	(159) - 0	81 - 148
Northern Rocky Mountains and Great Plains	Average over 21 years:	(4)	0	(4)	31
	Range in any year:	(12) - 6	0 - 0	(12) - 6	29 - 32
Northwest	Average over 21 years:	0	0	0	0
	Range in any year:	0 - 0	0 - 0	0 - 0	0 - 0
Western Interior	Average over 21 years:	0	0	0	14
	Range in any year:	0 - 1	0 - 0	0 - 1	14 - 14
U.S. Total	Average over 21 years:	(100)	(180)	(270)	620
	Range in any year:	(278) - (11)	(576) - (17)	(854) - (28)	525 - 686

[1] "Average over 21 years" is the average annual effect of the Alternative over the study period for the analysis on employment (2020-2040).
[2] "Range in any year" is the minimum and maximum effect on employment in any year in the study period.
[3] "Production-related employment effects" are calculated as effects associated with changes to coal production that are expected as a result of the Alternative. These are calculated using assumptions related to employment per ton of coal produced.
[4] The range of effects to Surface Employment represents the minimum and maximum effect in any year in the study period.
[5] The range of effects to Underground Employment represents the minimum and maximum effect in any year in the study period.
[6] The range of effects to Surface and Underground Combined employment represents the minimum and maximum impact in any year in the study period when the surface and underground mining effects are considered together. Because the minimum and maximum effects of the Alternative on surface and underground mining do not always occur in the same year, the Combined impact is not always equal to the sum of the Surface and Underground ranges.
[7] "Industry implementation-related employment effects" are calculated as effects associated with changes to expenditures on industry implementation-related activities and are calculated using assumptions related to employment demand per dollar spent on compliance.

Figure 4.3-1. Estimated Changes in Annual Employment under Alternative 2 Compared to the No Action Alternative, 2020-20140 (FTEs)



Notes: **"**Production-related" are effects on employment associated with changes to coal production that are expected as a result of Alternative 2. These are calculated using assumptions related to employment per ton of coal produced. The production-related job losses are associated only with the coal that is not produced because of changes associated with Alternative 2. This volume also becomes smaller over time given that the industry is getting smaller over time. "Industry implementation-related" are effects on employment calculated as effects associated with changes to expenditures related to industry implementation of the Alternative and are calculated using assumptions related to employment demand per dollar spent on compliance. The industry implementation-related employment effects are a function of all coal that is produced in any year in each region. Thus, the level of industry implementation-related job effects of Alternative 2 follow the pattern of overall forecasted coal production. As shown, both the industry implementation-related and the production-related impacts of the Alternative are reduced over time. However, the slopes of these curves are not the same.

Table 4.3-6. Estimated Changes in Annual Employment under Alternative 3 Compared to the No Action Alternative, 2020-2040 (FTEs)

Region	Metric	Production-Related Employment Effects[3] Surface[4]	Production-Related Employment Effects Underground[5]	Production-Related Employment Effects Surface and Underground Combined[6]	Industry implementation-related Employment Effects[7]
Appalachian Basin	Average over 21 years: [1]	(47)	(91)	(138)	246
	Range in any year: [2]	(181) - (1)	(351) - 0	(531) - (1)	209 - 270
Colorado Plateau	Average over 21 years:	0	0	0	13
	Range in any year:	(1) - 1	(1) - 1	(2) - 2	11 - 14

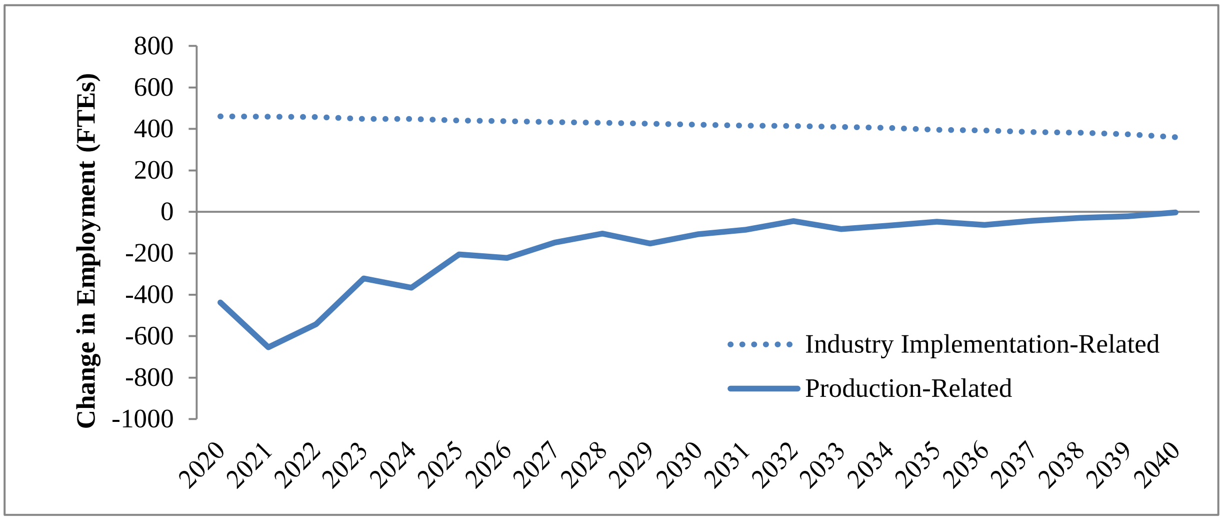
	Range in any year:	(5) - 5	0 – 0	(5) - 5	27 - 30
Northwest	Average over 21 years:	0	0	0	0
	Range in any year:	0 - 0	0 – 0	0 - 0	0 - 0
Western Interior	Average over 21 years:	0	0	0	9
	Range in any year:	0 - 0	0 – 0	0 - 0	9 - 9
U.S. Total	Average over 21 years:	(54)	(125)	(178)	419
	Range in any year:	(209) - (2)	(445) - 0	(654) - (2)	360 - 460

[1] "Average over 21 years" is the average annual effect of the Alternative over the study period for the analysis on employment (2020-2040).
[2] "Range in any year" is the minimum and maximum effect on employment in any year in the study period.
[3] "Production-related employment effects" are calculated as effects associated with changes to coal production that are expected as a result of the Alternative. These are calculated using assumptions related to employment per ton of coal produced.
[4] The range of effects to Surface Employment represents the minimum and maximum effect in any year in the study period.
[5] The range of effects to Underground Employment represents the minimum and maximum effect in any year in the study period.
[6] The range of effects to Surface and Underground Combined employment represents the minimum and maximum impact in any year in the study period when the surface and underground mining effects are considered together. Because the minimum and maximum effects of the Alternative on surface and underground mining do not always occur in the same year, the Combined impact is not always equal to the sum of the Surface and Underground ranges.
[7] "Industry implementation-related employment effects" are calculated as effects associated with changes to expenditures on industry implementation-related activities and are calculated using assumptions related to employment demand per dollar spent on compliance.

Figure 4.3-2. Estimated Changes in Total Annual Employment under Alternative 3 Compared to the No Action Alternative, 2020-2040 (FTEs)



Notes: **"**Production-related" are effects on employment associated with changes to coal production that are expected as a result of Alternative 3. These are calculated using assumptions related to employment per ton of coal produced. The production-related job losses are associated only with the coal that is not produced because of changes associated with Alternative 3. This volume also becomes smaller over time given that the industry is getting smaller over time. "Industry implementation-related" are effects on employment calculated as effects associated with changes to expenditures related to industry implementation of the Alternative and are calculated using assumptions related to employment demand per dollar spent on compliance. The industry implementation-related employment effects are a function of all coal that is produced in any year in each region. Thus, the level of industry implementation-related job effects of Alternative 3 follow the pattern of overall forecasted coal production. As shown, both the industry implementation-related and the production-related impacts of the Alternative are reduced over time. However, the slopes of these curves are not the same.

Table 4.3-7. Estimated Changes in Annual Employment under Alternative 4 Compared to the No Action Alternative, 2020-2040 (FTEs)

Region	Metric	Production-Related Employment Effects[3] Surface[4]	Production-Related Employment Effects Underground[5]	Production-Related Employment Effects Surface and Underground Combined[6]	Industry implementation-related Employment Effects[7]
Appalachian Basin	Average over 21 years: [1]	(37)	(77)	(114)	14
	Range in any year: [2]	(150) - (2)	(314) - (3)	(463) - (5)	12 - 16

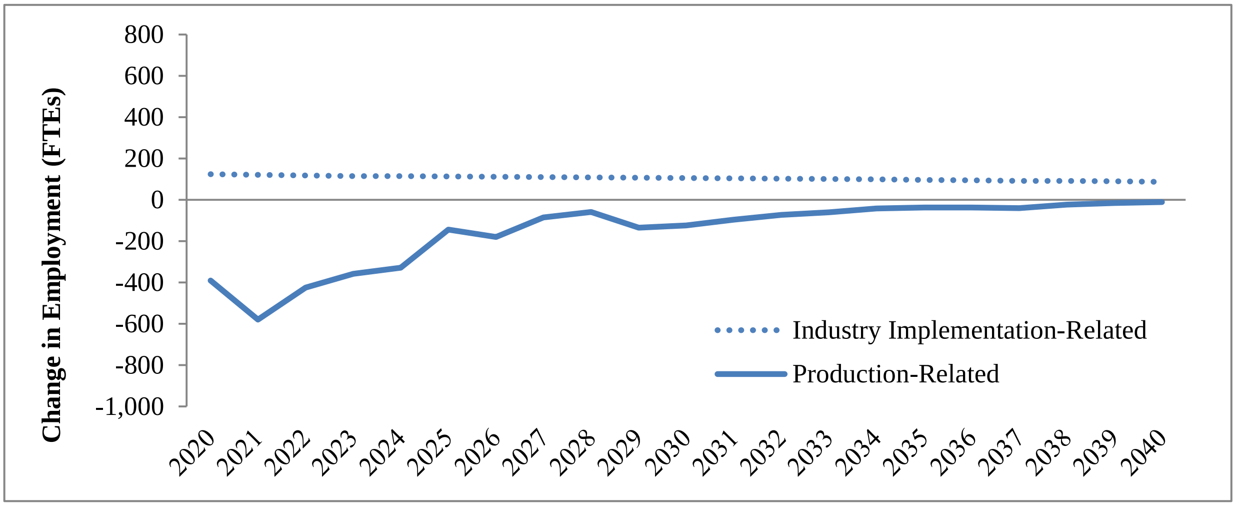
	Range in any year:	0 - 0	0 – 0	0 - 0	0 - 0
Western Interior	Average over 21 years:	0	0	0	7
	Range in any year:	0 - 0	0 – 0	0 - 0	7 - 7
U.S. Total	Average over 21 years:	(44)	(111)	(154)	105
	Range in any year:	(161) - (2)	(417) - (3)	(579) - (11)	88 - 124

[1] "Average over 21 years" is the average annual effect of the Alternative over the study period for the analysis on employment (2020-2040).
[2] "Range in any year" is the minimum and maximum effect on employment in any year in the study period.
[3] "Production-related employment effects" are calculated as effects associated with changes to coal production that are expected as a result of the Alternative. These are calculated using assumptions related to employment per ton of coal produced.
[4] The range of effects to Surface Employment represents the minimum and maximum effect in any year in the study period.
[5] The range of effects to Underground Employment represents the minimum and maximum effect in any year in the study period.
[6] The range of effects to Surface and Underground Combined employment represents the minimum and maximum impact in any year in the study period when the surface and underground mining effects are considered together. Because the minimum and maximum effects of the Alternative on surface and underground mining do not always occur in the same year, the Combined impact is not always equal to the sum of the Surface and Underground ranges.
[7] "Industry implementation-related employment effects" are calculated as effects associated with changes to expenditures on industry implementation-related activities and are calculated using assumptions related to employment demand per dollar spent on compliance.

Figure 4.3-3. Estimated Changes in Total Annual Employment under Alternative 4 Compared to the No Action Alternative, 2020-2040 (FTEs)



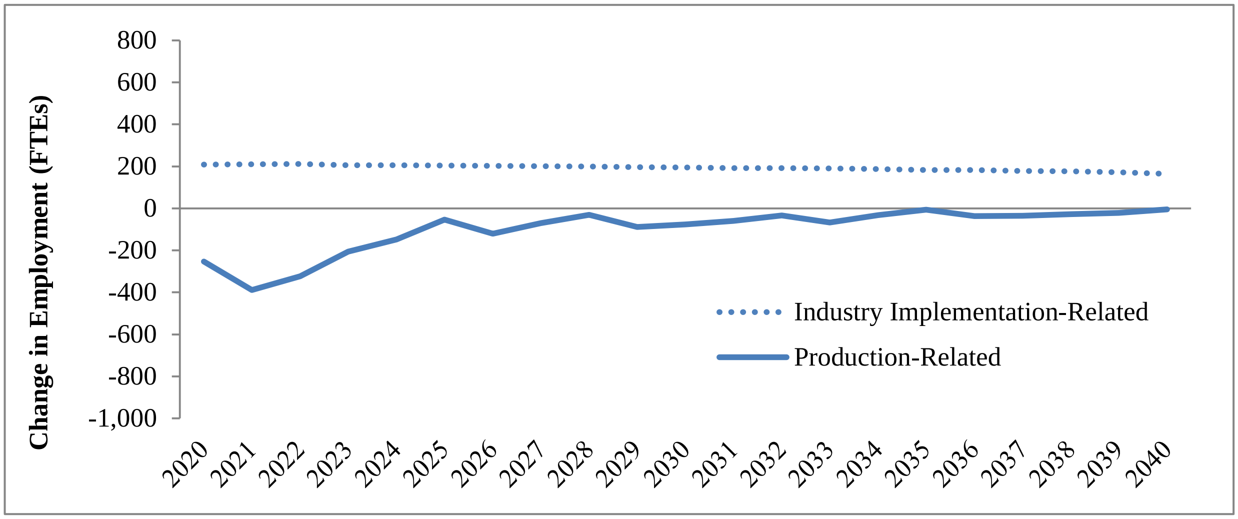
Notes: **"**Production-related" are effects on employment associated with changes to coal production that are expected as a result of Alternative 4. These are calculated using assumptions related to employment per ton of coal produced. The production-related job losses are associated only with the coal that is not produced because of changes associated with Alternative 4. This volume also becomes smaller over time given that the industry is getting smaller over time. "Industry implementation-related" are effects on employment calculated as effects associated with changes to expenditures related to industry implementation of the Alternative and are calculated using assumptions related to employment demand per dollar spent on compliance. The industry implementation-related employment effects are a function of all coal that is produced in any year in each region. Thus, the level of industry implementation-related job effects of Alternative 4 follow the pattern of overall forecasted coal production. As shown, both the industry implementation-related and the production-related impacts of the Alternative are reduced over time. However, the slopes of these curves are not the same.

Table 4.3-8. Estimated Changes in Annual Employment under Alternative 5 Compared to the No Action Alternative, 2020-2040 (FTEs)

Region	Metric	Production-Related Employment Effects[3] Surface[4]	Production-Related Employment Effects Underground[5]	Production-Related Employment Effects Surface and Underground Combined[6]	Industry implementation-related Employment Effects[7]
Appalachian Basin	Average over 21 years: [1]	(31)	(67)	(99)	193
	Range in any year: [2]	(125) - (1)	(257) – 0	(381) - (2)	164 - 212
Colorado Plateau	Average over 21 years:	0	0	0	0
	Range in any year:	(1) - 1	0 – 1	(1) - 2	0 - 0
Gulf Coast	Average over 21 years:	0	0	0	0
	Range in any year:	(6) - 7	0 – 0	(6) - 7	0 - 0
Illinois Basin	Average over 21 years:	0	0	0	0
	Range in any year:	(1) - 1	(7) – 7	(8) - 8	0 - 0
Northern Rocky Mountains and Great Plains	Average over 21 years:	(1)	0	(1)	0
	Range in any year:	(8) - 4	0 – 0	(8) - 4	0 - 0
Northwest	Average over 21 years:	0	0	0	0
	Range in any year:	0 - 0	0 – 0	0 - 0	0 - 0
Western Interior	Average over 21 years:	0	0	0	0
	Range in any year:	0 - 0	0 – 0	0 - 0	0 - 0
U.S. Total	Average over 21 years:	(32)	(67)	(99)	193
	Range in any year:	(125) - (4)	(263) – 0	(388) - (5)	164 - 212

[1] "Average over 21 years" is the average annual effect of the Alternative over the study period for the analysis on employment (2020-2040).
[2] "Range in any year" is the minimum and maximum effect on employment in any year in the study period.
[3] "Production-related employment effects" are calculated as effects associated with changes to coal production that are expected as a result of the Alternative. These are calculated using assumptions related to employment per ton of coal produced.
[4] The range of effects to Surface Employment represents the minimum and maximum effect in any year in the study period.
[5] The range of effects to Underground Employment represents the minimum and maximum effect in any year in the study period.
[6] The range of effects to Surface and Underground Combined employment represents the minimum and maximum impact in any year in the study period when the surface and underground mining effects are considered together. Because the minimum and maximum effects of the Alternative on surface and underground mining do not always occur in the same year, the Combined impact is not always equal to the sum of the Surface and Underground ranges.
[7] "Industry implementation-related employment effects" are calculated as effects associated with changes to expenditures on industry implementation-related activities and are calculated using assumptions related to employment demand per dollar spent on compliance.

Figure 4.3-4. Estimated Changes in Total Annual Employment under Alternative 5 Compared to the No Action Alternative, 2020-2040 (FTEs)



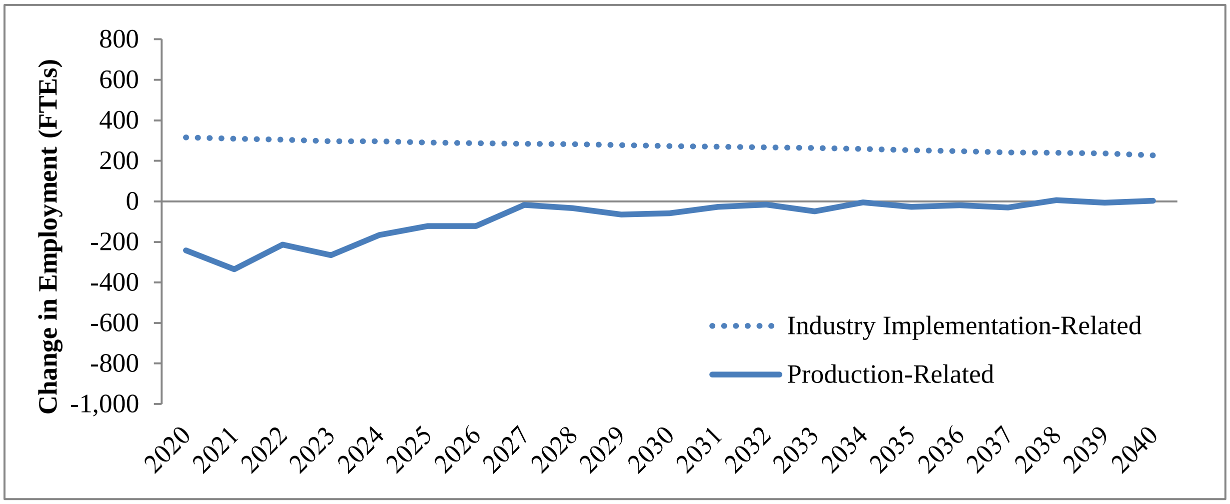
Notes: **"**Production-related" are effects on employment associated with changes to coal production that are expected as a result of Alternative 5. These are calculated using assumptions related to employment per ton of coal produced. The production-related job losses are associated only with the coal that is not produced because of changes associated with Alternative 5. This volume also becomes smaller over time given that the industry is getting smaller over time. "Industry implementation-related" are effects on employment calculated as effects associated with changes to expenditures related to industry implementation of the Alternative and are calculated using assumptions related to employment demand per dollar spent on compliance. The industry implementation-related employment effects are a function of all coal that is produced in any year in each region. Thus, the level of industry implementation-related job effects of Alternative 5 follow the pattern of overall forecasted coal production. As shown, both the industry implementation-related and the production-related impacts of the Alternative are reduced over time. However, the slopes of these curves are not the same.

Table 4.3-9. Estimated Changes in Annual Employment under Alternative 6 Compared to the No Action Alternative, 2020-2040 (FTEs)

Region	Metric	Production-Related Employment Effects[3] Surface[4]	Production-Related Employment Effects Underground[5]	Production-Related Employment Effects Surface and Underground Combined[6]	Industry implementation-related Employment Effects[7]
Appalachian Basin	Average over 21 years: [1]	(17)	(33)	(49)	88
	Range in any year: [2]	(81) - 0	(163) - 14	(244) - 12	75 - 95
Colorado Plateau	Average over 21 years:	0	0	0	8
	Range in any year:	(1) - 1	0 – 0	(1) - 1	7 - 8
Gulf Coast	Average over 21 years:	1	0	1	31
	Range in any year:	(12) - 13	0 – 0	(12) - 13	29 - 33
Illinois Basin	Average over 21 years:	(6)	(31)	(36)	114
	Range in any year:	(24) - 0	(104) - 0	(128) - 0	82 - 152
Northern Rocky Mountains and Great Plains	Average over 21 years:	(1)	0	(1)	17
	Range in any year:	(10) - 5	0 – 0	(10) - 5	16 - 18
Northwest	Average over 21 years:	0	0	0	1
	Range in any year:	0 - 0	0 – 0	0 - 0	0 - 1
Western Interior	Average over 21 years:	0	0	0	15
	Range in any year:	0 - 0	0 – 0	0 - 0	15 - 15
U.S. Total	Average over 21 years:	(23)	(63)	(86)	272
	Range in any year:	(88) - 4	(247) - 14	(335) - 7	227 - 315

[1] "Average over 21 years" is the average annual effect of the Alternative over the study period for the analysis on employment (2020-2040).
[2] "Range in any year" is the minimum and maximum effect on employment in any year in the study period.
[3] "Production-related employment effects" are calculated as effects associated with changes to coal production that are expected as a result of the Alternative. These are calculated using assumptions related to employment per ton of coal produced.
[4] The range of effects to Surface Employment represents the minimum and maximum effect in any year in the study period.
[5] The range of effects to Underground Employment represents the minimum and maximum effect in any year in the study period.
[6] The range of effects to Surface and Underground Combined employment represents the minimum and maximum impact in any year in the study period when the surface and underground mining effects are considered together. Because the minimum and maximum effects of the Alternative on surface and underground mining do not always occur in the same year, the Combined impact is not always equal to the sum of the Surface and Underground ranges.
[7] "Industry implementation-related employment effects" are calculated as effects associated with changes to expenditures on industry implementation-related activities and are calculated using assumptions related to employment demand per dollar spent on compliance.

Figure 4.3-5. Estimated Changes in Total Annual Employment under Alternative 6 Compared to the No Action Alternative, 2020-2040 (FTEs)



Notes: **"**Production-related" are effects on employment associated with changes to coal production that are expected as a result of Alternative 6. These are calculated using assumptions related to employment per ton of coal produced. The production-related job losses are associated only with the coal that is not produced because of changes associated with Alternative 6. This volume also becomes smaller over time given that the industry is getting smaller over time. "Industry implementation-related" are effects on employment calculated as effects associated with changes to expenditures related to industry implementation of the Alternative and are calculated using assumptions related to employment demand per dollar spent on compliance. The industry implementation-related employment effects are a function of all coal that is produced in any year in each region. Thus, the level of industry implementation-related job effects of Alternative 6 follow the pattern of overall forecasted coal production. As shown, both the industry implementation-related and the production-related impacts of the Alternative are reduced over time. However, the slopes of these curves are not the same.

Table 4.3-10. Estimated Changes in Annual Employment under Alternative 7 Compared to the No Action Alternative, 2020-2040 (FTEs)

Region	Metric	Production-Related Employment Effects[3] Surface[4]	Production-Related Employment Effects Underground[5]	Production-Related Employment Effects Surface and Underground Combined[6]	Industry implementation-related Employment Effects[7]

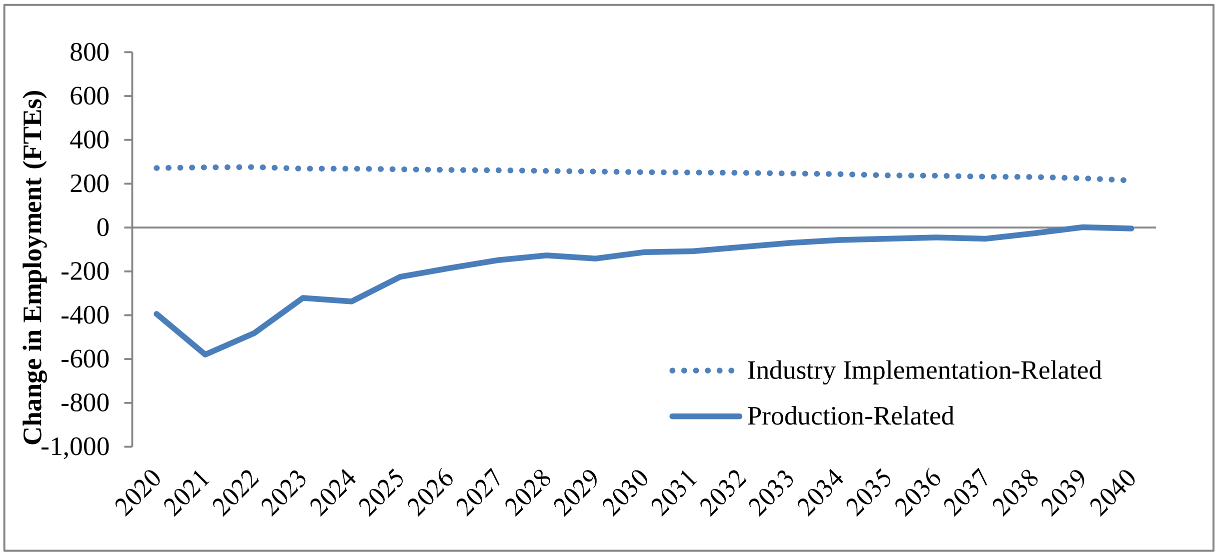
Western Interior	Average over 21 years:	0	0	0	1
	Range in any year:	0 - 0	0 – 0	0 - 1	1 - 1
U.S. Total	Average over 21 years:	(45)	(124)	(169)	252
	Range in any year:	(166) - 1	(413) – 1	(580) - 1	215 - 275

[1] "Average over 21 years" is the average annual effect of the Alternative over the study period for the analysis on employment (2020-2040).
[2] "Range in any year" is the minimum and maximum effect on employment in any year in the study period.
[3] "Production-related employment effects" are calculated as effects associated with changes to coal production that are expected as a result of the Alternative. These are calculated using assumptions related to employment per ton of coal produced.
[4] The range of effects to Surface Employment represents the minimum and maximum effect in any year in the study period.
[5] The range of effects to Underground Employment represents the minimum and maximum effect in any year in the study period.
[6] The range of effects to Surface and Underground Combined employment represents the minimum and maximum impact in any year in the study period when the surface and underground mining effects are considered together. Because the minimum and maximum effects of the Alternative on surface and underground mining do not always occur in the same year, the Combined impact is not always equal to the sum of the Surface and Underground ranges.
[7] "Industry implementation-related employment effects" are calculated as effects associated with changes to expenditures on industry implementation-related activities and are calculated using assumptions related to employment demand per dollar spent on compliance.

Figure 4.3-6. Estimated Changes in Total Annual Employment under Alternative 7 Compared to the No Action Alternative, 2020-2040 (FTEs)



Notes: **"**Production-related" are effects on employment associated with changes to coal production that are expected as a result of Alternative 7. These are calculated using assumptions related to employment per ton of coal produced. The production-related job losses are associated only with the coal that is not produced because of changes associated with Alternative 7. This volume also becomes smaller over time given that the industry is getting smaller over time. "Industry implementation-related" are effects on employment calculated as effects associated with changes to expenditures related to industry implementation of the Alternative and are calculated using assumptions related to employment demand per dollar spent on compliance. The industry implementation-related employment effects are a function of all coal that is produced in any year in each region. Thus, the level of industry implementation-related job effects of Alternative 7 follow the pattern of overall forecasted coal production. As shown, both the industry implementation-related and the production-related impacts of the Alternative are reduced over time. However, the slopes of these curves are not the same.

Table 4.3-11. Estimated Changes in Annual Employment under Alternative 8 (Preferred) Compared to the No Action Alternative, 2020-2040 (FTEs)

Region	Metric	Production-Related Employment Effects[3] Surface[4]	Production-Related Employment Effects Underground[5]	Production-Related Employment Effects Surface and Underground Combined[6]	Industry implementation-related Employment Effects[7]

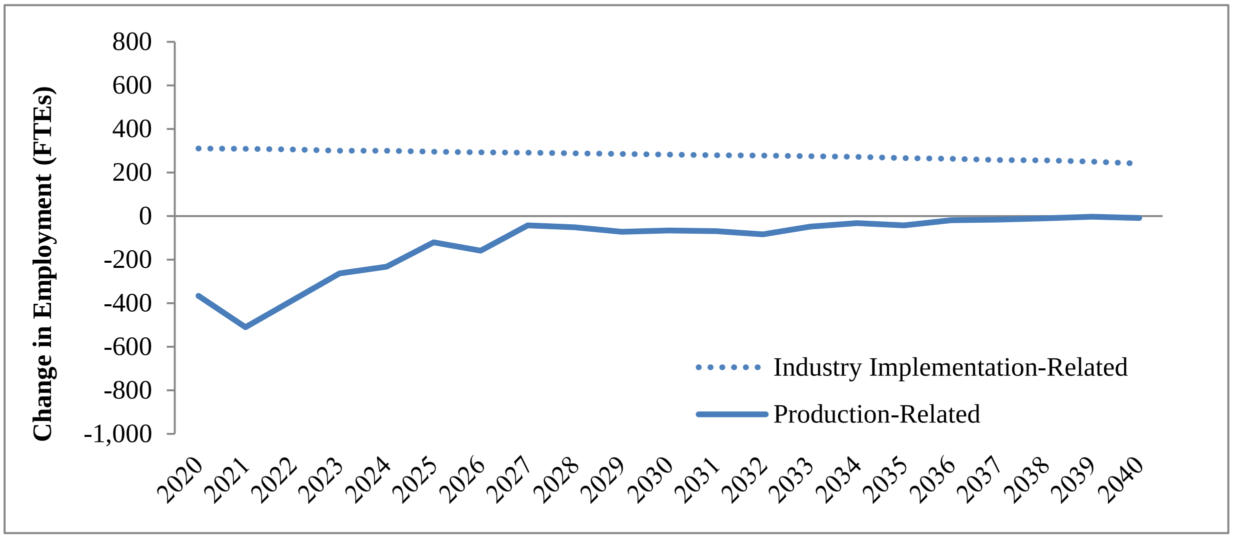
	Range in any year:	0 - 0	0 – 0	0 - 0	0 - 0
Western Interior	Average over 21 years:	0	0	0	8
	Range in any year:	0 - 0	0 – 0	0 - 0	8 - 8
U.S. Total	Average over 21 years:	(33)	(92)	(124)	280
	Range in any year:	(136) - (1)	(374) – 1	(511) - (3)	240 - 309

[1] "Average over 21 years" is the average annual effect of the Alternative over the study period for the analysis on employment (2020-2040).
[2] "Range in any year" is the minimum and maximum effect on employment in any year in the study period.
[3] "Production-related employment effects" are calculated as effects associated with changes to coal production that are expected as a result of the Alternative. These are calculated using assumptions related to employment per ton of coal produced.
[4] The range of effects to Surface Employment represents the minimum and maximum effect in any year in the study period.
[5] The range of effects to Underground Employment represents the minimum and maximum effect in any year in the study period.
[6] The range of effects to Surface and Underground Combined employment represents the minimum and maximum impact in any year in the study period when the surface and underground mining effects are considered together. Because the minimum and maximum effects of the Alternative on surface and underground mining do not always occur in the same year, the Combined impact is not always equal to the sum of the Surface and Underground ranges.
[7] "Industry implementation-related employment effects" are calculated as effects associated with changes to expenditures on industry implementation-related activities and are calculated using assumptions related to employment demand per dollar spent on compliance.

Figure 4.3-7. Estimated Changes in Total Annual Employment under Alternative 8 (Preferred) Compared to the No Action Alternative, 2020-2040 (FTEs)



Notes: **"**Production-related" are effects on employment associated with changes to coal production that are expected as a result of Alternative 8 (Preferred). These are calculated using assumptions related to employment per ton of coal produced. The production-related job losses are associated only with the coal that is not produced because of changes associated with Alternative 8 (Preferred). This volume also becomes smaller over time given that the industry is getting smaller over time. "Industry implementation-related" are effects on employment calculated as effects associated with changes to expenditures related to industry implementation of the Alternative and are calculated using assumptions related to employment demand per dollar spent on compliance. The industry implementation-related employment effects are a function of all coal that is produced in any year in each region. Thus, the level of industry implementation-related job effects of Alternative 8 (Preferred) follow the pattern of overall forecasted coal production. As shown, both the industry implementation-related and the production-related impacts of the Alternative are reduced over time. However, the slopes of these curves are not the same.

Table 4.3-12. Estimated Changes in Annual Employment (FTEs) under Alternative 9 Compared to the No Action Alternative

Region	Metric	Production-Related Employment Effects[3] Surface[4]	Production-Related Employment Effects[3] Underground[5]	Production-Related Employment Effects[3] Surface and Underground Combined[6]	Industry implementation-related Employment Effects[7]
Appalachian Basin	Average over 21 years: [1]	0	0	0	0
	Range in any year: [2]	0 - 0	0 – 0	0 - 0	0 - 0
Colorado Plateau	Average over 21 years:	0	0	0	0
	Range in any year:	0 - 0	0 – 0	0 - 0	0 - 0
Gulf Coast	Average over 21 years:	0	0	0	0
	Range in any year:	0 - 0	0 – 0	0 - 0	0 - 0
Illinois Basin	Average over 21 years:	0	0	0	0
	Range in any year:	0 - 0	0 – 0	0 - 0	0 - 0
Northern Rocky Mountains and Great Plains	Average over 21 years:	0	0	0	0
	Range in any year:	0 - 0	0 – 0	0 - 0	0 - 0
Northwest	Average over 21 years:	0	0	0	0
	Range in any year:	0 - 0	0 – 0	0 - 0	0 - 0
Western Interior	Average over 21 years:	0	0	0	0
	Range in any year:	0 - 0	0 – 0	0 - 0	0 - 0
U.S. Total	Average over 21 years:	0	0	0	0
	Range in any year:	0 - 0	0 – 0	0 - 0	0 - 0

[1] "Average over 21 years" is the average annual effect of the Alternative over the study period for the analysis on employment (2020-2040).
[2] "Range in any year" is the minimum and maximum effect on employment in any year in the study period.
[3] "Production-related employment effects" are calculated as effects associated with changes to coal production that are expected as a result of the Alternative. These are calculated using assumptions related to employment per ton of coal produced.
[4] The range of effects to Surface Employment represents the minimum and maximum effect in any year in the study period.
[5] The range of effects to Underground Employment represents the minimum and maximum effect in any year in the study period.
[6] The range of effects to Surface and Underground Combined employment represents the minimum and maximum impact in any year in the study period when the surface and underground mining effects are considered together. Because the minimum and maximum effects of the Alternative on surface and underground mining do not always occur in the same year, the Combined impact is not always equal to the sum of the Surface and Underground ranges.
[7] "Industry implementation-related employment effects" are calculated as effects associated with changes to expenditures on industry implementation-related activities and are calculated using assumptions related to employment demand per dollar spent on compliance.

4.3.1.5 Regional Income Impacts Analysis

The employment impacts from the Action Alternatives may affect regional income in some areas. These effects would be felt most in areas where coal mining contributes heavily to overall employment. Table 4.3-13 reports 2014 coal mining employment and annual payroll by state. Compared to other states, coal mining employment and payroll contributes most to employment in West Virginia and Wyoming, rendering these states most closely tied to shifts in coal production in those states. Income effects may also be felt most heavily in areas experiencing a relatively large shift in production as a result of an Action Alternative. In some parts of the Appalachian Basin region, the coal mining industry provides some of the highest-paying jobs in poor, rural communities. A decrease in mining-related employment may cut off an important source of income in areas that are primarily dependent on coal mining. This analysis estimates effects of each Action Alternative on labor income in coal regions based on the expected regional shifts in production and employment when compared to the No Action Alternative. Labor income is a measure of the employment income received in coal regions as part of the demand for employment, and includes wages, benefits, and proprietor income.

The analysis undertakes the following steps to estimate effects on labor income:

1. **Derive annual salaries:** The first step involves using the IMPLAN model to estimate typical annual salaries for workers for each region across all Alternatives.

2. **Apply salary coefficients to employment impacts:** The second step involves applying the estimated annual salaries to estimates of employment impacts by region. This generates estimates of the effects on labor income associated with employment effects of the Action Alternative. Impacts to labor income under the Action Alternatives represent the difference from labor income projections under the No Action Alternative, and may be adverse or beneficial. The analysis examines labor income effects from both production-related impacts and industry implementation-related impacts to employment.

Some increases in employment demand due to work requirements imposed on mining operations by the Action Alternatives could occur. These additional work requirements include performing inspections, conducting biological assessments, and other tasks that require employment of highly trained professionals (e.g., engineers and biologists) as part of compliance with some elements of the Action Alternatives. Other increased work requirements associated with elements contained in the Action Alternatives are expected to require similar skills as currently used by the industry (e.g., bulldozer operations). In general, while some of the increased employment demand may use existing mining labor skills (e.g., requirements that require additional earth moving), other employment demand from Action Alternatives may require other types of labor (e.g., biological monitoring, lab testing, paperwork). As noted above, some additional jobs created by the Action Alternatives may differ in skill requirements from the production-oriented jobs that would be reduced due to decreased coal production.

Estimated effects on labor income are directly associated with estimated effects on employment. Impacts to labor income may be beneficial in some years due to additional labor required for mine operations to achieve compliance with the Action Alternatives. Table 4.3-14 through Table 4.3-21 report the ranges of estimated impacts to annual labor income expected to result from the Action Alternatives. In sum:

- Under Alternative 2, production-related impacts to annual labor income are expected to range from an adverse impact of $71 million to an adverse impact of $2.4 million nationally. Industry implementation-related impacts are expected to range from an increase of $44 million to $57 million nationally;
- Alternative 3 is expected to result in production-related impacts to annual labor income ranging from negative $54 million to negative $0.2 million. Industry implementation-related impacts are expected to range from an increase of $30 million to $38 million nationally;
- Alternative 4 is expected to lead to production-related impacts to annual labor income nationwide, ranging from an adverse impact of $48 million to an adverse impact of $1.0 million. Industry implementation-related impacts are expected to range from an increase of $7.4 million to $10 million nationally;
- The production-related impacts to annual labor income under Alternative 5 range from negative $32 million to negative $0.4 million. Industry implementation-related impacts are expected to range from an increase of $14 million to $18 million nationally;
- Under Alternative 6, the production-related impacts are expected to range from a negative $28 million to a positive $0.5 million. Industry implementation-related impacts are expected to range from an increase of $19 million to $26 million nationally;
- Under Alternative 7, production-related impacts to annual labor income were determined to range from an adverse impact of $48 million to a positive impact of $0.1 million. Industry implementation-related impacts are expected to range from an increase of $18 million to $23 million nationally;
- Under Alternative 8 (Preferred), production-related impacts to annual labor income were determined to range from an adverse impact of $42 million to an adverse impact of $0.3 million. Industry implementation-related impacts are expected to range from an increase of $20 million to $26 million nationally;
- Finally, under Alternative 9, impacts to annual labor income are equivalent to the No Action Alternative. For comparison, Table 4.3-13 presents 2014 coal mining industry payroll at over $7 billion.

Table 4.3-13. Coal Mining Employment and Annual Payroll by State, 2014

Geography	Number of Coal Industry Employees [1]	Contribution of Coal Industry Employees to Total Employment (%)[2]	Coal Industry Employment Growth 2005 - 2014 (%)[1]	Coal Industry Annual Payroll 2014 ($1000)	Coal Industry Contribution to Total State Annual Payroll (%)[4]	Coal Industry Payroll Growth 2005 - 2014 (%)[3]

[1] "Average over 21 years" is the average annual effect of the Alternative over the study period for the analysis on labor income.
[2] "Range in any year" is the minimum and maximum effect on labor income in any year in the study period.
[3] "Production-Related Labor Income Effects" are calculated as effects associated with changes to coal production that are expected as a result of the Alternative. These are calculated using assumptions related to employment per ton of coal produced and labor income per FTE.
[4] The range of effects to labor income related to "Surface" represents the minimum and maximum effect in any year in the study period.
[5] The range of effects to labor income related to "Underground" represents the minimum and maximum effect in any year in the study period.
[6] The range of effects to labor income related to "Surface and Underground Combined" represents the minimum and maximum impact in any year in the study period when the surface and underground mining effects are considered together. Because the minimum and maximum effects of the Alternative on surface and underground mining do not always occur in the same year, the Combined impact is not always equal to the sum of the Surface and Underground ranges.
[7] "Industry implementation-related Labor Income Effects" are calculated as effects associated with changes to expenditures on industry implementation-related activities and are calculated using assumptions related to employment demand per dollar spent on compliance and labor income per FTE.

Table 4.3-15. Estimated Changes in Annual Labor Income (Millions of dollars) Under Alternative 3 Compared to the No Action Alternative

	Range in any year:	($0.7) - $0.4	$0.0 - $0.0	($0.7) - $0.4	$3.5 - $3.8
Illinois Basin	Average over 21 years:	($0.5)	($2.8)	($3.3)	$6.4
	Range in any year:	($1.9) - ($0.0)	($8.4) - ($0.1)	($10.0) - ($0.1)	$4.7 - $8.3
Northern Rocky Mountains and Great Plains	Average over 21 years:	($0.0)	$0.0	$0.0	$2.7
	Range in any year:	($0.4) - $0.4	$0.0 - $0.0	($0.4) - $0.4	$2.6 - $2.9
Northwest	Average over 21 years:	$0.0	$0.0	$0.0	$0.0
	Range in any year:	$0.0 - $0.0	$0.0 - $0.0	$0.0 - $0.0	$0.0 - $0.0
Western Interior	Average over 21 years:	$0.0	$0.0	$0.0	$0.8
	Range in any year:	$0.0 - $0.0	$0.0 - $0.0	$0.0 - $0.0	$0.7 - $0.8
U.S. Total	Average over 21 years:	($4.5)	($10.0)	($15.0)	$35.0
	Range in any year:	($17.0) - ($0.2)	($37.0) - ($0.0)	($54.0) - ($0.2)	$30.0 - $38.0

[1] "Average over 21 years" is the average annual effect of the Alternative over the study period for the analysis on labor income.
[2] "Range in any year" is the minimum and maximum effect on labor income in any year in the study period.
[3] "Production-Related Labor Income Effects" are calculated as effects associated with changes to coal production that are expected as a result of the Alternative. These are calculated using assumptions related to employment per ton of coal produced and labor income per FTE.
[4] The range of effects to labor income related to "Surface" represents the minimum and maximum effect in any year in the study period.
[5] The range of effects to labor income related to "Underground" represents the minimum and maximum effect in any year in the study period.
[6] The range of effects to labor income related to "Surface and Underground Combined" represents the minimum and maximum impact in any year in the study period when the surface and underground mining effects are considered together. Because the minimum and maximum effects of the Alternative on surface and underground mining do not always occur in the same year, the Combined impact is not always equal to the sum of the Surface and Underground ranges.
[7] "Industry implementation-related Labor Income Effects" are calculated as effects associated with changes to expenditures on industry implementation-related activities and are calculated using assumptions related to employment demand per dollar spent on compliance and labor income per FTE.

Table 4.3-16. Estimated Changes in Annual Labor Income (Millions of dollars) Under Alternative 4 Compared to the No Action Alternative

Region	Metric	Production-Related Labor Income Effects[3] Surface[4]	Production-Related Labor Income Effects[3] Underground[5]	Production-Related Labor Income Effects[3] Surface and Underground Combined[6]	Industry implementation-related Labor Income Effects[7]
Appalachian Basin	Average over 21 years:[1]	($3.1)	($6.4)	($9.5)	$1.2
	Range in any year:[2]	($12.0) - ($0.2)	($26.0) - ($0.2)	($39.0) - ($0.4)	$1.0 - $1.3
Colorado Plateau	Average over 21 years:	$0.0	$0.0	$0.0	$0.0
	Range in any year:	($0.1) - $0.1	($0.1) - $0.0	($0.1) - $0.1	$0.4 - $0.4
Gulf Coast	Average over 21 years:	($0.0)	$0.0	($0.0)	$0.0
	Range in any year:	($1.3) - $0.8	$0.0 - $0.0	($1.3) - $0.8	$1.6 - $1.8
Illinois Basin	Average over 21 years:	($0.5)	($2.8)	($3.3)	$3.8
	Range in any year:	($1.8) - $0.0	($8.5) - ($0.0)	($10.0) - ($0.0)	$2.6 - $5.3
Northern Rocky Mountains and Great Plains	Average over 21 years:	$0.1	($0.0)	$0.1	$1.1
	Range in any year:	($0.5) - $0.8	$0.0 - $0.0	($0.5) - $0.8	$1.0 - $1.2
Northwest	Average over 21 years:	$0.0	$0.0	$0.0	$0.0
	Range in any year:	$0.0 - $0.0	$0.0 - $0.0	$0.0 - $0.0	$0.0 - $0.0
Western Interior	Average over 21 years:	$0.0	$0.0	$0.0	$0.6
	Range in any year:	$0.0 - $0.0	$0.0 - $0.0	$0.0 - $0.0	$0.6 - $0.6
U.S. Total	Average over 21 years:	($3.6)	($9.2)	($13.0)	$8.8
	Range in any year:	($13.0) - ($0.1)	($35.0) - ($0.3)	($48.0) - ($1.0)	$7.4 - $10.0

[1] "Average over 21 years" is the average annual effect of the Alternative over the study period for the analysis on labor income.
[2] "Range in any year" is the minimum and maximum effect on labor income in any year in the study period.
[3] "Production-Related Labor Income Effects" are calculated as effects associated with changes to coal production that are expected as a result of the Alternative. These are calculated using assumptions related to employment per ton of coal produced and labor income per FTE.
[4] The range of effects to labor income related to "Surface" represents the minimum and maximum effect in any year in the study period.
[5] The range of effects to labor income related to "Underground" represents the minimum and maximum effect in any year in the study period.
[6] The range of effects to labor income related to "Surface and Underground Combined" represents the minimum and maximum impact in any year in the study period when the surface and underground mining effects are considered together. Because the minimum and maximum effects of the Alternative on surface and underground mining do not always occur in the same year, the Combined impact is not always equal to the sum of the Surface and Underground ranges.
[7] "Industry implementation-related Labor Income Effects" are calculated as effects associated with changes to expenditures on industry implementation-related activities and are calculated using assumptions related to employment demand per dollar spent on compliance and labor income per FTE.

Table 4.3-17. Estimated Changes in Annual Labor Income (Millions of dollars) Under Alternative 5 Compared to the No Action Alternative

Region	Metric	Production-Related Labor Income Effects[3] Surface[4]	Production-Related Labor Income Effects[3] Underground[5]	Production-Related Labor Income Effects[3] Surface and Underground Combined[6]	Industry implementation-related Labor Income Effects[7]

U.S. Total	Average over 21 years:	$0	$0	$0	$0
	Range in any year:	$0 - $0	$0 - $0	$0 - $0	$0 - $0

1 "Average over 21 years" is the average annual effect of the Alternative over the study period for the analysis on labor income.
2 "Range in any year" is the minimum and maximum effect on labor income in any year in the study period.
3 "Production-Related Labor Income Effects" are calculated as effects associated with changes to coal production that are expected as a result of the Alternative. These are calculated using assumptions related to employment per ton of coal produced and labor income per FTE.
4 The range of effects to labor income related to "Surface" represents the minimum and maximum effect in any year in the study period.
5 The range of effects to labor income related to "Underground" represents the minimum and maximum effect in any year in the study period.
6 The range of effects to labor income related to "Surface and Underground Combined" represents the minimum and maximum impact in any year in the study period when the surface and underground mining effects are considered together. Because the minimum and maximum effects of the Alternative on surface and underground mining do not always occur in the same year, the Combined impact is not always equal to the sum of the Surface and Underground ranges.
7 "Industry implementation-related Labor Income Effects" are calculated as effects associated with changes to expenditures on industry implementation-related activities and are calculated using assumptions related to employment demand per dollar spent on compliance and labor income per FTE.

4.3.1.6 Property Value Impacts Analysis

Table 4.3-22 reports median home value in the coal regions in recent years. With the exception of the Northwest region, the median home value is lower within coal regions than in states as a whole.[38] Section 4.1 describes shifts in coal production expected under each of the Action Alternatives. A number of factors could contribute to property value effects associated with Action Alternatives at localized scale. These could include the following:

- More stringent requirements regarding topography and revegetation of reclaimed lands in the Action Alternatives may result in landscapes that resemble premining conditions more than would have been expected under the No Action Alternative. To the extent that buyers prefer a more natural landscape, property value benefits could occur in localized areas.[39]
- Improved water quality near particular properties may also benefit property values (Poor, et al., 2007). These improvements may also benefit property values by increasing the quality or quantity of recreational opportunities that are available.
- If the rule results in reduced coal employment in a region, communities that are dependent on coal production (e.g., in the Appalachian Basin), could see demand for housing decline, with associated property value reductions on a local scale.
- When approximate original contour (AOC) variances are obtained, land is sometimes flattened in preparation for farming or development. If requirements of some Action Alternatives lead to fewer AOC variances, then they may reduce these opportunities, decreasing the resale value of the land.

Given the site-specific and contrasting potential effects of the Action Alternatives on property values, it is not possible to predict the direction of any impacts on property values at a regional or national scale.

---

[38] Statewide home values include urban and rural areas. Because coal mining largely occurs in rural areas, statewide home values may be an imperfect point of comparison, i.e., part of the differential attributed to coal mining may reflect a more general urban/rural disparity.

[39] These changes are similar to impacts achieved by low-impact development techniques, which have been demonstrated to improve property values (Ward, et al., 2008).

Table 4.3-22. Median Home Value in Coal Regions, 2011

Coal Region[1]	Geography	Median Home Value[2]
Appalachian Basin	Within Region	$112,413
	Statewide	$174,551
Colorado Plateau	Within Region	$193,367
	Statewide	$209,077
Gulf Coast	Within Region	$96,084
	Statewide	$125,170
Illinois Basin	Within Region	$130,478
	Statewide	$163,414
Northern Rocky Mountains and Great Plains	Within Region	$199,665
	Statewide	$213,776
Northwest	Within Region	$394,197
	Statewide	$278,629
Western Interior	Within Region	$104,353
	Statewide	$122,718
U.S. Total	Within All Regions	$151,493
	Nationwide	$186,200

Source: U.S. Census Bureau, 2011a. American Community Survey 2007-2011 Five-Year Estimates.
[1] Statistics presented in the non-shaded rows account only for coal-producing counties within the coal region. Statewide statistics account for all states intersecting the coal region.
[2] Median reported value of owner-occupied housing units.
Note: This information is provided as background information in support of the discussions contained within the EIS. OSMRE has not updated this information since publication of the DEIS.

4.3.1.7 Tax Revenue Impacts Analysis

Severance tax revenue is directly related to the level of coal mining production activity. Thus, regulatory alternatives that reduce production in a given region will result in reduced severance tax revenues. Conversely, increased coal production would generate increased severance tax revenues. The precise relationship between coal production and severance tax revenues is complicated in some states. For example, some states only tax certain types of coal extracted or offer credits for particular extraction methods. For this reason, this analysis undertakes the following method to estimate impacts of the Action Alternatives on state tax revenues:

1. **Derive effective tax rates.** The first step involves examining state tax codes for coal severance taxation rates. For some states, the severance tax rate is a simple dollar-per-ton multiplier, but many states vary the tax rate for different types of coal mining or provide tax credits and exemptions for certain types of mining. Some states calculate severance tax based on the gross value of severed coal.

2. **Apply effective tax rates to production forecasted.** The second step involves multiplying the effective tax rates by estimates of future production for each state. The difference between estimated severance tax revenues under the Action Alternatives and baseline revenue forecasts represents the impact of the Final Rule to state severance tax revenues.

3. **Derive annualized impacts.** The final step involves calculating the present value of tax revenue impacts in 2014 dollars, and annualizing the present value over the entire period of study. The analysis uses discount rates of three and seven percent (see RIA Appendix G).

Table 4.3-24 presents tax rates on coal severance by state. In order to create a forecast of potential impacts of the Action Alternatives on coal severance tax collections, an attempt was made to use reported tax rates to estimate actual total state severance tax collections. For states where estimates were accurate within a ten percent error bound, the analysis uses reported tax rates to estimate future severance tax revenues based on coal production projections.

In four states, the method for estimating severance tax revenues using reported tax rates resulted in estimates that differed by more than ten percent from actual reported revenues. These states (West Virginia, Arkansas, Montana, and Colorado) have tax provisions that make it difficult to forecast future revenues based on reported tax rates. For these states, the analysis uses an alternate production-to-tax-revenue multiplier to estimate future coal severance tax collections. This multiplier was calculated by dividing recent (2012) severance tax revenues by coal production levels in the same year. Table 4.3-24 presents the estimated tax rates used in this analysis for these states.

Table 4.3-23 reports recent severance tax revenues by state. In total, $935 million was collected in severance tax revenues across all coal-producing states. West Virginia and Kentucky are estimated to bear over 95 percent of the lost severance tax revenues. These estimates are conservative for West Virginia and Kentucky as they are based on historic per-ton tax revenues while West Virginia and Kentucky severance taxes are based on the price of coal. As coal prices are expected to increase during the study period due to the Final Rule, the coal severance tax impacts of the Final Rule may be less than estimated here for West Virginia and Kentucky.

Estimated state coal severance tax impacts depend both on the severance tax rate and the magnitude of estimated production impacts. Tables 4.3-25 through Table 4.3-27 report estimated coal severance tax impacts by state and region. Impacts are reported as a total present value (in 2014 dollars) of all impacts over the study period, as well as annualized over 2020 to 2040 with a seven percent discount rate. Nationally, Alternative 2 is expected to result in an annualized decrease in state coal severance tax revenues of $2.4 million. Under Alternative 3, the decrease in coal severance tax revenues is expected to be $1.6 million annually. Alternative 4 is expected to result in an annualized decrease in coal severance tax revenues of $1.3 million. Annualized decreases in national coal severance tax under Alternatives 5, 6, and 7 were calculated to be approximately $0.9 million, $0.7 million, and $1.0 million, respectively. Under Alternative 8 (Preferred), the decrease in national coal severance tax revenues is also expected to be nearly $1.0 million. Severance tax revenues are not expected to change from the base case under Alternative 9.

Table 4.3-23. Recent Coal Severance Tax Revenues Collected by State, (Millions of dollars)

State	Coal Severance Tax Revenues	Total State Tax Revenues	Contribution of Coal Severance to Total Taxes
Appalachian Basin			
Alabama[1]	$5.0	$9,294	0.05%

[1] State Coal Severance Tax Revenues are reported for the FY ending September 30, 2015. Total State Tax Revenues are reported for the calendar year ending December 31, 2014. These tax values do not include revenues collected by Tribal governments.
[2] State Coal Severance Tax Revenues are reported for the FY ending June 30, 2015. The Total State Tax Revenues are reported for the calendar year ending December 31, 2014. These tax values do not include revenues collected by Tribal governments.
[3] State Coal Severance Tax Revenues are reported for the FY ending June 30, 2012. Total State Tax Revenues are reported for the calendar year ending December 31, 2014. These tax values do not include revenues collected by Tribal governments.
[4] State does not collect coal severance taxes.

Notes:
Alaska - Severance tax revenues listed are those by the Usibelli Coal Mine, the only active coal mine in the state (accessed at http://www.usibelli.com/pdf/McDowell-Report-Statewide-Socioeconomic-Impacts-of-UCM-2015l.pdf).
Arkansas - Severance tax revenues were not available for FY 2015 and the values listed represent FY 2012.
Kansas - Coal severance tax revenues are reported as a percentage of the Special County Mineral Tax Production Fund, which also includes oil and gas. Kansas collected $8.5 million in this tax in the FY ending on June 30, 2015, but no tax revenues have been attributed to coal in recent years (Kansas Department of Revenue Annual Report, 2016).
Kentucky and Colorado - Two coal mining regions are present in Kentucky (Appalachia and Illinois Basin) and Colorado (Northern Rocky Mountains and Great Plains). Severance tax revenues are reported as a statewide total. Therefore, it is not possible to determine the severance tax contributions by each of the two coal mining regions in these states. As such, severance tax collections for Kentucky and Colorado are presented as being split evenly between the two coal regions they overlap, respectively.
New Mexico - Severance tax revenues listed are net of the Intergovernmental Tax Credits (ITC) afforded to taxed coal entities.
Virginia - While counties and municipalities may impose taxes on coal extracted, no coal severance tax revenues were reported in 2015.

Table 4.3-24. Reported Coal Severance Tax Rates by State

State	Severance Tax Type	Rate	Assumed Rate
Appalachian Basin			
Alabama[1]	State Coal Severance Tax	$0.335 per ton for the state.	$0.335 per ton
	Local Coal Severance Tax	$0.20 per ton in Jackson and Marshall County.	$0.335 per ton
Kentucky[1]	Coal Severance and Processing Tax	4.5% of gross value with a minimum tax of $0.50 per ton. A credit is given to thin seam coal extraction on a scale from 2.25% to 3.75% of the coal value.	$3.00 per ton for surface production and $2.88 per ton for underground production.
Maryland	No Coal Severance Tax	NA	
Ohio[1]	Coal Severance Tax	Base rate of $0.10 per ton, plus an additional $0.012 per ton on surface mined coal. An additional $0.12 to $0.16 per ton is levied on operations without a full cost bond and changes based on the amount remaining in the state Reclamation Forfeiture Fund at the end of each state budget biennium.	$0.252 per ton for surface production and $0.24 per ton for underground production.
Pennsylvania	No Coal Severance Tax	NA	
Tennessee[1]	Coal Severance Tax	$0.75 per ton on entire production of coal products in the state, regardless of place of sale or outside-of-state delivery.	$0.75 per ton
Virginia	Local Coal Reclamation Tax	Any county or city may impose a severance tax on all coal within its jurisdiction. The rate of tax shall not exceed 1% of the gross receipts from such coal or gases.	
West Virginia[2]	Natural Resources Severance Tax	5% of gross value, with the following reduced rates for thin seam underground mining: 2% of gross value for seams with thickness between 37 and 45 inches and 1% of gross value for seams with thickness less than 37 inches.	$3.757 per ton
Colorado Plateau			
Arizona	No Coal Severance Tax	NA	
Colorado[2]	Coal Severance Tax	$0.842 per ton.	$0.542 per ton.
New Mexico[1]	Coal Severance Tax	$0.57 per ton on surface coal and $0.55 per ton on underground coal. The state also imposes a surtax on coal, which is increased on July 1 each year. The surtax in effect in Fiscal Year 2009 was $0.83 per ton. Post-2011 renegotiated contracts are not subject to the surtax.	$1.40 per ton for surface production and $1.38 per ton rate for underground production ($0.57/$0.55 per ton rate plus $0.83 per ton surtax).*
Utah	No Coal Severance Tax	NA	
Gulf Coast			
Louisiana[1]	Natural Resources Severance Tax	$0.12 per ton of lignite.	$0.12 per ton
Mississippi	No Coal Severance Tax	NA	
Texas	No Coal Severance Tax	NA	
Illinois Basin

[1]Production in Kentucky is evenly divided between the Appalachian Basin and Illinois Basin regions.
Note: All numbers rounded to three significant figures

Outside of state taxes, two excise taxes are imposed by the federal government: The Abandoned Mine Lands Reclamation Tax (also known as the reclamation fee or AML fee) and the Black Lung Excise Tax (BLET). Whether these taxes will continue to be imposed prior to and during the study period is uncertain.[40] If either or both taxes are collected during the study period, revenue from them would be less than under the No Action Alternative because of reductions in coal production. The reclamation fee imposes a tax of $0.28 per ton of coal produced by surface mining, $0.12 per ton of coal produced by underground mining, $0.08 per ton for lignite (30 U.S.C. § 1232).[41] The Black Lung Excise Tax is taxed at a rate of $1.10 on coal from underground mines, and $0.55 on coal from surface mines, not to exceed 4.4 percent of coal sold by the producer (26 U.S.C. § 4121). The expected revenue from these taxes would vary because of differences in tax rates for surface and underground and from the differences in declines in coal tonnages for surface and underground mining. Less revenue would not necessarily result in short-falls for miner's compensation fund because the incidence of Black Lung would likely be reduced with reduced exposure to underground mining.

To the extent that taxes other than severance taxes, (such as ad valorem taxes, workers compensation taxes, corporate income taxes, sales and use taxes, AML fee, and BLET), are related to the level of coal production, regulatory alternatives that reduce production in a given region will result in reduced tax revenues. The precise relationship between coal production and tax revenues varies by tax type, and the overall impacts of the Action Alternatives on the revenues collected from these taxes would be difficult to track with certainty, as taxes are levied differently within states, often varying by County. However, as forecast elsewhere in this analysis, Action Alternatives are anticipated to reduce coal production. On average, the annual reduction in coal production across the Action Alternatives ranges from a decrease of 0.0 million tons (under Alternative 9) to a decrease of 1.3 million tons (under Alternative 2). , this decrease represents less than one percent of current (2015) U.S production. Thus, as is the case with severance tax impacts, the scale of impacts of changes to coal production is anticipated to be small. While some county and local governments rely heavily on the revenues from taxes on coal and other natural resource extraction, expected impacts of the Action Alternatives on these revenue streams will be relatively small. To illustrate the potential impacts of the Action Alternatives on these other taxes, OSMRE uses the example of ad valorem taxes in Wyoming and Alternative 8 (Preferred). Wyoming collected approximately $240 million in ad valorem taxes on coal production in Fiscal Year 2015, with an average tax per unit of $0.59 for surface coal, and $1.78 for underground coal. [42] Under Alternative 8 (Preferred), the average annual projected decrease in coal production in Wyoming is anticipated to be 0.7 million tons of coal between 2020 to 2040 (in the primary base case). As such, Alternative 8 (Preferred) would be expected to result in an annual reduction in ad valorem tax revenue across all recipient Wyoming counties of approximately $23,000 annually ($2014, seven percent discount rate). This would represent a decrease, when compared with Wyoming ad valorem tax revenues collected in 2015, of approximately 0.01 percent.

[40] Collection of the reclamation fee is scheduled to end September 30, 2021 (30 U.S.C. § 1232(a)).

[41] The reclamation fee may be based on a percentage of the value of the coal if that specified percentage is less than the per ton rate (30 U.S.C. 1232(a)).

Additional taxes are contingent on the value of coal sales or coal property rather than on the value or level of production. These taxes include property taxes, workers compensation taxes, corporate income taxes, and sales and use taxes. These taxes would be reduced when corporate revenues and/or employment is reduced. Impacts on these taxes are not quantified in the analysis, but are anticipated to be small given the overall scale of the anticipated impacts of the Action Alternatives on coal production.

4.3.1.8 Quality of Life Impacts Analysis

The coal mining industry has historically brought high-paying jobs to rural areas, particularly in parts of Central Appalachia. The Action Alternatives may impact the quality of life in coal-producing regions either through regional shifts in coal production or overall reduction of coal produced when compared to the No Action Alternative. A decrease in overall coal production caused by the Action Alternatives would contribute to the recent downward trend in coal industry production, putting further stress on communities already experiencing economic distress. A decrease in coal mining activity may threaten not only the primary source of income and health insurance in some areas, but also the sense of community and identity associated with the mining culture. After generations of working in coal mines, many Appalachian Basin communities still maintain social and cultural connections with the coal industry, even as the number of mining jobs has decreased. A reduction in coal production may weaken social networks in rural areas that have traditionally depended on coal mining. Depending on the severity of the observed changes, declining quality of life in coal-dependent communities could lead to population declines in those communities.

Some Action Alternatives also introduce new restrictions on postmining land use (see Section 4.3.2). With more reclaimed land returned to its AOC and vegetation, developers in coal-producing regions may have reduced access to sources of flat, developable land, which can be a scarce resource in mountainous coal-producing areas. This decrease in developable land has the potential to restrict future economic growth in parts of the country already undergoing economic hardship.

A decrease in coal mining may also improve the quality of life in some areas by reducing some of the adverse impacts associated with coal mining. Decreased prevalence of mining and construction operations would decrease the amount of traffic and noise affecting residents of coal-producing areas. More land in coal-producing regions would be left in its original state, improving landscape ecology and visual aesthetics. Finally, reduced coal mining activity may lessen anxiety over possible adverse health impacts attributed to living near coal mining.

4.3.1.9 Summary of Effects

Table 4.3-28 presents the impacts of the Action Alternatives relative to the No Action Alternative. Impact determinations consider the length of impact, geographic scope of impact, and potential for offsetting the impact. As described in Section 4.0.3, for socioeconomic conditions, impacts of the Action Alternatives on employment and income, tax revenues, property values, quality of life, and demographics are evaluated. Some impacts of the Alternatives would be short-term on a per-mine basis, and other impacts would be expected to extend beyond the period of active mining (long-term). Determinations of the intensity of impacts on socioeconomic resources considered the impacts of the Action Alternatives on employment and income, tax revenues, property values, quality of life, and demographics. Indicators of impacts on quality of life and demographics are likely to be linked to impacts on employment and income in each region and, to a lesser degree, impacts on tax revenues. Specifically, determinations were made using the following analytical categories:

- Negligible: Minimal measurable impacts (adverse or beneficial) are expected; or short term effects to a small geographic area, community or economy.
- Minor adverse or beneficial: A few individuals, groups, businesses, properties, or institutions could be affected. Impacts would be small and localized. The impacts are not expected to substantively alter social and/or economic conditions.
- Moderate adverse or beneficial: Many individuals, groups, businesses, properties, or institutions could be affected. Impacts could be readily apparent and detectable in local and adjacent areas and could have a noticeable effect on social and/or economic conditions.
- Major adverse or beneficial: A large proportion of individuals, groups, businesses or other institutions would experience a change in economic or social conditions as an obvious result of an action. Impacts could extend over a widespread area. The effect could have a substantial influence on social and/or economic conditions.

In order to be conservative, i.e., more likely to overstate impacts than understate them, the analysis determines impacts to employment focusing on the anticipated changes in production-related employment in each region.[43] The "Overall Impact to Socioeconomics" is the expected overall effect on socioeconomic resources, combining the expected impacts to employment income, quality of life and expected impacts to taxes on coal production.[44]

At the national scale, Alternative 2 is anticipated to result in Moderate Adverse impacts on socioeconomic conditions including, in particular, employment and severance taxes when compared to the No Action Alternative. Alternatives 3, 4, 5, 6, 7, and 8 (Preferred) are anticipated to result in Minor Adverse impacts on socioeconomic conditions, including employment, and severance taxes at the national scale. Alternative 9 is anticipated to be functionally similar to the No Action Alternative and is anticipated to result in Negligible effects on socioeconomic conditions.

At a regional scale, Major Adverse impacts on socioeconomic conditions, including employment, are anticipated in the Appalachian Basin under Alternative 2. Moderate Adverse impacts on socioeconomic conditions are anticipated in the Appalachian Basin under Alternatives 3, 4, 5, 7, and 8 (Preferred). Impacts to other regions to socioeconomic conditions are anticipated to be Minor Adverse or Negligible across Alternatives at the regional scale when compared to the No Action Alternative.

4.3.1.9.1 Alternative 1 (No Action Alternative)

Under the No Action Alternative, no further regulations or corrective measures in addition to those already in place would be implemented. Therefore, ongoing trends in socioeconomic conditions would continue. Mining under the No Action Alternative would continue to provide employment, income and tax revenues at current levels and would only change due to normal market conditions that are applicable to all the Alternatives.

[43] Potential increases in employment demand related to compliance activities are also anticipated.

[44] "Overall Impact to Socioeconomics" is the expected overall effect on socioeconomic resources, combining the expected impacts to employment, income, quality of life and taxes on coal production

The annual quantity of coal demanded and associated production is anticipated to be approximately 10 percent lower in 2040 than in 2020 without implementation of the Alternatives (i.e., under the No Action Alternative). In particular, the Colorado Plateau, Appalachian Basin, and Northern Rocky Mountain and Great Plains regions are forecasted to have the largest production decreases in coal production, respectively. This reduction in production would be expected to have adverse impacts on localized socioeconomics conditions, to the extent that reductions in coal production also reduce coal mining employment and associated income. Reduced coal production volume would also reduce tax collections by regional governments. These decreases could result in depressed localized property values, and could result in adverse impacts to quality of life in communities that are dependent on coal production. However, property values also have the potential to increase as aesthetics improve in localized areas. Reduced noise and impacts to visual resources could also lead to benefits to quality of life in some areas, particularly if some areas become more attractive for recreational activities under the No Action Alternative.

4.3.1.9.2 Alternative 2

Due to the stringency and broad applicability of the requirements under Alternative 2, this alternative is expected to have the largest effect on coal production across the examined Action Alternatives and is therefore generally expected to result in the greatest impacts to socioeconomic resources, including employment, income, and coal severance tax revenues. These impacts are greatest in the Appalachian Basin, which bears the majority of costs under Alternative 2. Because of the importance of the coal mining industry to the Appalachian Basin and because of its current economic distress due to a recent downward trend in coal production regionally, the incremental adverse impacts on socioeconomic resources, such as employment, income and tax revenues, due to Alternative 2 may further reduce the quality of life. For these reasons, the Appalachian Basin is expected to experience Major Adverse impacts to socioeconomic resources under Alternative 2. Impacts on coal production are significantly lower in the Illinois Basin and the Northern Rocky Mountains and Great Plains regions, and therefore impacts to socioeconomic resources are expected to be minor relative to the No Action Alternative. Because the amount of coal produced is not expected to materially change in the other regions of Colorado Plateau, Gulf Coast, Northwest, and Western Interior, changes to socioeconomic resources, including employment, income, coal-based tax revenues, property values and quality of life, are expected to be Negligible in these regions.

At the national level, Alternative 2 is classified as Moderate Adverse because it is expected to generate impacts that could be readily apparent and detectable in local and adjacent areas and could have a noticeable effect on social and/or economic conditions across many individuals, groups, businesses, properties, or institutions, particularly in the Appalachian Basin. In the following sections, the impacts of Alternative 2 on socioeconomic resources are discussed in more detail by region.

4.3.1.9.2.1 Appalachian Basin

Appalachian mines, especially surface mines, incur the highest costs under Alternative 2 and as a result, Alternative 2 is expected to result in the largest reduction in coal mining activity in the Appalachian Basin (when compared to the other Action Alternatives), an average of approximately 0.8 million tons annually, or 0.4 percent of baseline production in this region (MSHA, 2015). As a result of these reductions in the amount of coal produced, Alternative 2 is also expected to decrease regional employment, labor income, and coal severance tax revenues relative to the No Action Alternative. For example, in the Appalachian Basin under Alternative 2, adverse impacts to socioeconomic resources include potential reductions in coal industry employment and severance tax revenues. Expected production-related employment effects are anticipated to comprise 0.5 percent of 2014 Appalachian Basin coal mining employment (U.S. EIA, 2016a), and projected reductions in severance tax revenues represent 0.7 percent of recent severance taxes collected annually in this region (see Table 4.3-23 for sources). Additional permitting requirements of the rule may increase demand for employment, though some of the requirements may require different skills than those in traditional coal mining positions.

As discussed previously, the coal mining industry has historically brought high-paying jobs to rural areas, particularly in parts of Central Appalachia. A decrease in overall coal production under Alternative 2 may place further stresses on communities already experiencing economic distress from the recent downward trend in coal industry production. Of note, in some parts of the Appalachian Basin coal mining provides one of few sources of income. Given the historical social and cultural connections between the Appalachian Basin and the coal industry, further reductions in employment, income and tax collections under Alternative 2 may weaken social networks in rural areas that have traditionally depended on coal mining. Depending on the severity of the observed changes within a community, declining quality of life in coal-dependent communities could lead to population declines in those communities. For these reasons, the impacts of Alternative 2 on socioeconomic resources in the Appalachian Basin are considered Major Adverse.

4.3.1.9.2.2 Illinois Basin and Northern Rocky Mountains and Great Plains

The implementation of Alternative 2 is expected to generate moderate reductions in coal mining activity in the Illinois Basin region and minor reductions in the Northern Rocky Mountains and Great Plains region. In the Illinois Basin, Alternative 2 is expected to reduce coal mining activity by an average of 0.4 million tons annually, equal to approximately 0.4 percent of baseline production in this region (MSHA, 2015). In the Northern Rocky Mountains and Great Plans, coal production is expected to fall by an average of 0.1 million tons per year under Alternative 2, equal to approximately 0.03 percent of baseline regional production (MSHA, 2015). Accordingly, production-related employment losses are expected to be relatively minor under this alternative, accounting for 0.4 and 0.04 percent of coal mining employment in the Illinois Basin, and Northern Rocky Mountains and Great Plains regions, respectively (U.S. EIA, 2016a). Impacts on coal severance tax revenues are expected to be relatively Negligible in both regions. For these reasons, the impacts of Alternative 2 on socioeconomic resources in the Illinois Basin, and Northern Rocky Mountains and Great Plains regions are expected to be Minor Adverse.

4.3.1.9.2.3 Other Regions

As discussed in Section 4.1, implementation of Alternative 2 is expected to generate negligible changes in the amount of coal produced in the Colorado Plateau, Gulf Coast, Northwest, and Western Interior regions, a loss no greater than 0.1 million tons annually. Because the amount of coal produced is not expected to change by a significant amount, changes to socioeconomic resources, including employment, income, coal-based tax revenues, property values and quality of life, are expected to be Negligible as well in these regions.

4.3.1.9.3 Alternative 3

Alternative 3 is expected to result in a moderate decrease in coal production. Compared to Alternative 2, the general direction of impacts remains the same, but the scope is diminished, due primarily to the more moderate decrease in coal production, specifically in the Appalachian Basin. Accordingly, at the national level, Alternative 3 is classified as Minor Adverse because the adverse impacts are expected to be localized to the Appalachian Basin and impacts to socioeconomic resources in the remaining regions are classified as either Minor Adverse or Negligible. In the following sections, the impacts of Alternative 3 on socioeconomic resources are discussed in more detail by region.

4.3.1.9.3.1 Appalachian Basin

Under Alternative 3, the Appalachian Basin accounts for the majority (nearly 50 percent) of compliance costs and as a result, Alternative 3 is expected to result in moderate reductions in coal mining activity in the Appalachian Basin, an average of approximately 0.5 million tons annually, or 0.2 percent of baseline regional production (MSHA, 2015). As a result of these reductions in the amount of coal produced, Alternative 3 is also expected to decrease regional employment, labor income and coal severance tax revenues relative to the No Action Alternative. For example, in the Appalachian Basin region under Alternative 3, adverse impacts to socioeconomic resources also include potential reductions in coal industry employment and severance tax revenues. Expected production-related employment effects are anticipated to comprise 0.3 percent of 2014 regional coal mining employment (U.S. EIA, 2016a), and projected reductions in severance tax revenues represent 0.5 percent of recent regional severance taxes collections annually (see Table 4.3-23 for sources). Additional permitting requirements of the rule may increase demand for employment, though some of the requirements may require different skills than those in traditional coal mining positions.

As discussed previously, the coal mining industry has historically brought high-paying jobs to rural areas, particularly in parts of Central Appalachia. Further decreases in employment, income and tax collections under Alternative 3 may place further stresses on coal-dependent communities in the Appalachian Basin already experiencing economic distress from the recent downward trend in coal industry production. Such adverse socioeconomic impacts could in turn precipitate an overall decline in the quality of life in these communities. For these reasons, the impacts of Alternative 3 on socioeconomic resources in the Appalachian Basin are expected to be Moderate Adverse.

4.3.1.9.3.2 Illinois Basin

The implementation of Alternative 3 is expected to generate moderate reductions in coal mining activity in the Illinois Basin region. In the Illinois Basin, Alternative 3 is expected to reduce coal mining activity by an average of 0.3 million tons annually, equal to approximately 0.3 percent of baseline regional production (MSHA, 2015). Accordingly, expected production-related employment losses are expected to be relatively minor under this alternative, accounting for 0.3 percent of coal mining employment in the Illinois Basin region (U.S. EIA, 2016a). Impacts to coal severance tax revenues are expected to be relatively Negligible in both regions. For these reasons, the impacts of Alternative 3 on socioeconomic resources in the Illinois Basin, and Northern Rocky Mountains and Great Plains regions are expected to be Minor Adverse.

4.3.1.9.3.3 Other Regions

As discussed in Section 4.1, implementation of Alternative 3 is expected to generate negligible changes in the amount of coal produced in the Colorado Plateau, Gulf Coast, Northern Rocky Mountains and Great Plains, Northwest and Western Interior regions, a loss no greater than 0.1 million tons annually. Because the amount of coal produced is not expected to change significantly, changes to socioeconomic resources, including employment, income, coal-based tax revenues, property values and quality of life, are expected to be Negligible as well in these regions.

4.3.1.9.4 Alternative 4

Alternative 4 is expected to result in moderate reductions in coal production, and is therefore generally expected to result in similar impacts to socioeconomic resources across the Action Alternatives as described for Alternative 3. Similar to Alternative 3, at the national level, Alternative 4 is classified as Minor Adverse because the adverse impacts are expected to be localized to the Appalachian Basin and impacts to socioeconomic resources in the remaining regions are classified as either Minor Adverse or Negligible. In the following sections, the impacts of Alternative 4 on socioeconomic resources are discussed in more detail by region.

4.3.1.9.4.1 Appalachian Basin

The costs of implementing Alternative 4 in the Appalachian Basin are similar to Alternative 3. Specifically, Alternative 4 is expected to produce moderate reductions in coal mining activity in the Appalachian Basin, an average of approximately 0.4 million tons annually, or 0.2 percent of baseline regional production (MSHA, 2015). Under Alternative 4, adverse impacts to socioeconomic resources from reduced mining activities also include potential reductions in coal industry employment and severance tax revenues. Expected production-related employment effects are anticipated to comprise 0.3 percent of regional coal mining employment (U.S. EIA, 2016a), and projected reductions in severance tax revenues represent 0.4 percent of recently collected annual coal severance tax revenues in this region (see Table 4.3-23 for sources). Additional permitting requirements of the rule may increase demand for employment, though some of the requirements may require different skills than those in traditional coal mining positions.

As discussed previously, the coal industry has played a crucial role in the development and support of communities in the Appalachian Basin. As a result, decreases in employment, income and tax collections under Alternative 4 may further diminish property values and precipitate a decline in the overall quality of life in these communities. For these reasons, the effects of Alternative 4 in the Appalachian Basin are expected to be Moderate Adverse.

4.3.1.9.4.2 Illinois Basin and Northern Rocky Mountains and Great Plains

The implementation of Alternative 4 is expected to generate moderate reductions in coal mining activity in the Illinois Basin region and minor reductions in the Northern Rocky Mountains and Great Plains region. In the Illinois Basin, Alternative 4 is expected to reduce coal mining activity by an average of 0.3 million tons annually, equal to approximately 0.3 percent of baseline regional production (MSHA, 2015). In the Northern Rocky Mountains and Great Plans, coal production is expected to change by an annual average of less than 0.1 million tons per year under Alternative 4, equal to approximately 0.01 percent of baseline regional production (MSHA, 2015). Accordingly, production-related employment losses are expected to be relatively minor under this alternative, accounting for 0.3 and 0.01 percent of coal mining employment in the Illinois Basin, and Northern Rocky Mountains and Great Plains regions, respectively. Impacts on coal severance tax revenues are expected to be relatively Negligible in both regions. For these reasons, the Illinois Basin, and Northern Rocky Mountains and Great Plains regions are expected to experience Minor Adverse impacts on socioeconomic resources under Alternative 4.

4.3.1.9.4.3 Other Regions

As discussed in Section 4.1, implementation of Alternative 4 is expected to generate negligible changes in the amount of coal produced in the Colorado Plateau, Gulf Coast, Northwest, and Western Interior regions, a loss no greater than 0.1 million tons annually. Because the amount of coal produced is not expected to change significantly, changes to socioeconomic resources, including employment, income, coal-based tax revenues, property values and quality of life, are expected to be Negligible as well in these regions.

4.3.1.9.5 Alternative 5

Alternative 5 is expected to result in the least reductions in coal production across the Action Alternatives (with the exception of Alternative 9 in which no reductions are expected). At the national level, Alternative 5 is classified as Minor Adverse because the adverse impacts are expected to be localized to the Appalachian Basin and impacts to socioeconomic resources in the remaining regions are classified as Negligible. In the following sections, the impacts of Alternative 5 on socioeconomic resources are discussed in more detail, by region.

4.3.1.9.5.1 Appalachian Basin

Similar to Alternatives 2, 3, and 4, the costs of implementing Alternative 5 is expected to produce moderate reductions in surface and underground coal mining activities in the Appalachian Basin, an average of 0.4 million tons annually, or 0.2 percent of baseline regional production (MSHA, 2015). Reduced mining would decrease regional employment, labor income and coal severance tax revenues relative to the No Action Alternative. Specifically, adverse impacts to production-related employment are anticipated to comprise 0.2 percent of regional coal mining employment (U.S. EIA, 2016a), and projected reductions in annual severance tax revenues represent 0.3 percent of recently collected revenues in this region under Alternative 5. Additional permitting requirements of the rule may increase demand for employment, though some of the requirements may require different skills than those in traditional coal mining positions.

As discussed previously, the coal industry has played a crucial role in the development and support of communities in the Appalachian Basin. As a result, expected decreases in employment, income and tax collections under Alternative 5 may further diminish property values and precipitate a decline in the overall quality of life in these communities. For these reasons, the Appalachian Basin region is predicted to experience a Moderate Adverse impact under Alternative 5.

4.3.1.9.5.2 Northern Rocky Mountains and Great Plains

The implementation of Alternative 5 is expected to generate minor reductions in coal mining activity in the Northern Rocky Mountains and Great Plains region. Under Alternative 5, coal production is expected to fall by an average of less than 0.1 million tons annually, equal to approximately 0.01 percent of baseline regional production (MSHA, 2015). These reductions translate to relatively minor employment losses, accounting for 0.01 percent of coal mining employment in this region (U.S. EIA, 2016a). Impacts on coal severance tax revenues are expected to be Negligible. For these reasons, the Northern Rocky Mountains and Great Plains region is anticipated to incur Minor Adverse impacts to socioeconomic resources under Alternative 5.

4.3.1.9.5.3 Other Regions

As discussed in Section 4.1, implementation of Alternative 5 is expected to generate negligible changes in the amount of coal produced in the Illinois Basin, Colorado Plateau, Gulf Coast, Northwest, and Western Interior regions, a loss no greater than 0.1 million tons annually. Because the amount of coal produced is not expected to change significantly, changes to socioeconomic resources, including employment, income, coal-based tax revenues, property values and quality of life, are expected to be Negligible as well in these regions.

4.3.1.9.6 Alternative 6

Alternative 6 is expected to result in moderate reductions in coal production, slightly less than those expected to occur under Alternative 4. Accordingly, at the national level, Alternative 6 is classified as Minor Adverse because, across all coal regions, only a few individuals, groups, businesses, properties, or institutions would be affected and impacts would be small and localized. Accordingly, the impacts are not expected to substantively alter social and/or economic conditions. In the following sections, the impacts of Alternative 6 on socioeconomic resources are discussed in more detail, by region.

4.3.1.9.6.1 Appalachian Basin

Although Alternative 6 prohibits mining activities within 100 feet of intermittent or perennial streams, it allows regulatory authorities to approve placement of excess spoil or coal mine waste in an intermittent or perennial stream under certain conditions. As these conditions are prevalent in the Appalachian Basin, the overall costs of complying with Alternative 6 are relatively lower in this region. For example, Alternative 6 is estimated to reduce coal mining by an average of approximately 0.2 million tons annually in the Appalachian Basin, equivalent to nearly 0.1 percent of baseline regional production (MSHA, 2015). These reductions translate to only minor impacts to socioeconomic resources. For example, impacts to production-related employment under Alternative 6 are anticipated to comprise 0.1 percent of regional coal mining employment (U.S, EIA, 2016a), and projected reductions in annual severance tax revenues represent 0.2 percent of recently collected regional coal severance tax revenues (see Table 4.3-23 for sources). Accordingly, Alternative 6 is not expected to substantively alter social and/or economic conditions impacts on property values and quality of life. For these reasons, the effects of Alternative 6 in the Appalachian Basin are expected to be Minor Adverse.

4.3.1.9.6.2 Illinois Basin and Northern Rocky Mountains and Great Plains

Impacts to socioeconomic resources under Alternative 6 in the Illinois Basin and Northern Rocky Mountains and Great Plains regions are expected to be of a similar magnitude as under the other Alternatives. Coal production is expected to fall by an average of 0.3 million tons annually in the Illinois Basin, equal to approximately 0.3 percent of regional baseline production (MSHA, 2015). This level of reduced mining activity translates to production-related employment losses comprising 0.3 percent of coal mining employment in this region (U.S. EIA, 2016a). In the Northern Rocky Mountains and Great Plains region, coal production is expected to fall by an average of less than 0.1 million tons annually. This reduction results in minor impacts to employment, comprising 0.01 percent of regional coal mining employment (U.S. EIA, 2016a). Severance tax revenue impacts are expected to be Negligible in these regions. For these reasons, the impacts of Alternative 6 on socioeconomic resources in these regions are considered Minor Adverse.

4.3.1.9.6.3 Other Regions

As discussed in Section 4.1, implementation of Alternative 6 is expected to generate negligible changes in the amount of coal produced in the Colorado Plateau, Gulf Coast, Northwest, and Western Interior regions, a loss no greater than 0.1 million tons annually. Because the amount of coal produced is not expected to change significantly, changes to socioeconomic resources, including employment, income, coal-based tax revenues, property values and quality of life, are expected to be Negligible as well in these regions.

4.3.1.9.7 Alternative 7

Alternative 7 is expected to result in moderate reductions in coal production. At the national level, Alternative 7 is classified as Minor Adverse because the adverse impacts are expected to be localized to the Appalachian Basin and impacts to socioeconomic resources in the remaining regions are classified as either Minor Adverse or Negligible. In the following sections, the impacts of Alternative 7 on socioeconomic resources are discussed in more detail, by region.

4.3.1.9.7.1 Appalachian Basin

Under Alternative 7, additional permitting requirements are focused on a smaller subset of mining operations involving factors that OSMRE has determined pose additional risk to the environment and warrant enhanced permitting requirements (e.g., steep slope areas, and riparian areas). Because the conditions warranting enhanced permitting requirements exist throughout most of the Appalachian Basin, Alternative 7 is predicted to generate Moderate Adverse impacts to socioeconomic resources in this region. Specifically, Alternative 7 is expected to produce moderate reductions in coal mining activity in the Appalachian Basin, an average of approximately 0.4 million tons annually, or 0.2 percent of regional baseline production (MSHA, 2015). Additional permitting requirements of the rule may increase demand for employment, though some of the requirements may require different skills than those in traditional coal mining positions. Adverse impacts to production-related employment are anticipated to comprise 0.3 percent of regional coal mining employment (U.S. EIA, 2016a), and projected reductions in annual severance tax revenues represent 0.4 percent of recently collected regional coal severance tax revenues under Alternative 7 (see Table 4.3-23 for sources).

As discussed previously, the coal industry has played a crucial role in the development and support of communities in the Appalachian Basin. As a result, decreases in employment, income and tax collections under Alternative 7 may weaken the identity and culture in these communities that have traditionally depended on coal mining. Such adverse impacts may reduce demand for living in these communities which can in turn reduce property values and precipitate a decline in the overall quality of life in these communities.

4.3.1.9.7.2 Illinois Basin and Northern Rocky Mountains and Great Plains

The implementation of Alternative 7 is expected to generate moderate reductions in coal mining activity in the Illinois Basin and minor reductions in Northern Rocky Mountains and Great Plains regions. In the Illinois Basin, Alternative 7 is expected to reduce coal mining activity by an average of approximately 0.4 million tons annually, equal to approximately 0.3 percent of regional baseline production (MSHA, 2015). In the Northern Rocky Mountains and Great Plans, coal production is expected to change by an average of less than 0.1 million tons per year under Alternative 7, equal to less than 0.01 percent of baseline regional production. Accordingly, in both the Illinois Basin and Northern Rocky Mountains and Great Plains regions, employment is expected to experience only a minor decrease over the No Action Alternative. Specifically, impacts to production-related employment are expected to comprise 0.4 and 0.01 percent of regional coal mining employment, respectively (U.S. EIA, 2016a). Impacts to coal severance tax revenues are expected to be Negligible in both the Illinois Basin and the Northern Rocky Mountains and Great Plains region. For these reasons, the overall impact assessment of socioeconomic resources is Minor Adverse for both regions.

4.3.1.9.7.3 Other Regions

As discussed in Section 4.1, implementation of Alternative 7 is expected to generate negligible changes in the amount of coal produced in the Colorado Plateau, Gulf Coast, Northwest, and Western Interior regions, a loss no greater than 0.1 million tons annually. Because the amount of coal produced is not expected to change significantly, changes to socioeconomic resources, including employment, income, coal-based tax revenues, property values and quality of life, are expected to be Negligible as well in these regions.

4.3.1.9.8 Alternative 8 (Preferred)

Alternative 8 (Preferred) is expected to result in moderate reductions in coal production, and is therefore generally expected to result in similar impacts to socioeconomic resources across the Action Alternatives as described for Alternative 4. At the national level, Alternative 8 (Preferred) is classified as Minor Adverse because the adverse impacts are expected to be localized to the Appalachian Basin and impacts to socioeconomic resources in the remaining regions are classified as either Minor Adverse or Negligible. In the following sections, the impacts of Alternative 8 (Preferred) on socioeconomic resources are discussed in more detail, by region.

4.3.1.9.8.1 Appalachian Basin

Under Alternative 8 (Preferred), the Appalachian Basin accounts for the majority (approximately 40 percent) of compliance costs and as a result, Alternative 8 (Preferred) is expected to result in a moderate reduction in coal mining activity in the Appalachian Basin, an average of approximately 0.4 million tons annually, or 0.1 percent of baseline regional production (MSHA, 2015). As a result of these reductions in mining activity, Alternative 8 (Preferred) is also expected to decrease regional employment, labor income and coal severance tax revenues relative to the No Action Alternative. For example, under Alternative 8 (Preferred), adverse impacts to production-related employment are anticipated to comprise nearly 0.2 percent of regional coal mining employment (U.S. EIA, 2016a), and projected reductions in annual severance tax revenues represent nearly 0.3 percent of recently collected regional severance taxes collected (see Table 4.3-23 for sources). Additional permitting requirements of the rule may increase demand for employment, though some of the requirements may require different skills than those in traditional coal mining positions.

As discussed previously, the coal mining industry has historically brought high-paying jobs to rural areas, particularly in parts of Central Appalachia. Further decreases in employment, income and tax collections under Alternative 8 (Preferred) may place further stresses on coal-dependent communities in the Appalachian Basin which are already experiencing economic distress from the recent downward trend in coal industry production. Such adverse socioeconomic impacts may weaken the identity and culture in these communities that have traditionally depended on coal mining leading to an overall decline in the quality of life in these communities. For these reasons, the impacts of Alternative 8 (Preferred) on socioeconomic resources in the Appalachian Basin are expected to be Moderate Adverse.

4.3.1.9.8.2 Illinois Basin and Northern Rocky Mountains and Great Plains

As under Alternative 4, decreases in coal production under Alternative 8 (Preferred) are expected to be moderate in the Illinois Basin region and minor in the Northern Rocky Mountains and Great Plains region relative to the No Action Alternative. In the Illinois Basin, Alternative 8 (Preferred) is expected to reduce coal mining activity by an average of approximately 0.3 million tons annually, equal to approximately 0.3 percent of regional baseline production (MSHA, 2015). In the Northern Rocky Mountains and Great Plans, coal production is expected to fall an average of less than 0.1 million tons per year under Alternative 8 (Preferred), equal to approximately 0.02 percent of regional baseline production (MSHA, 2015). As a result of these relatively minor reductions in coal production, socioeconomic resources in the Illinois Basin and Northern Rocky Mountains and Great Plains regions are expected to experience Minor Adverse impacts under Alternative 8 (Preferred). This overall impact is driven by minor employment impacts in the Northern Rocky Mountains and Great Plains region and is a combination of minor impacts to both employment and severance tax revenues in the Illinois Basin.

4.3.1.9.8.3 Other Regions

As discussed in Section 4.1, implementation of Alternative 8 (Preferred) is expected to generate negligible changes in the amount of coal produced in the Colorado Plateau, Gulf Coast, Northwest and Western Interior regions, a loss no greater than 0.1 million tons annually. Because the amount of coal produced is not expected to change significantly, changes to socioeconomic resources, including employment, income, coal-based tax revenues, property values and quality of life, are expected to be Negligible as well in these regions.

4.3.1.9.9 Alternative 9

4.3.1.9.9.1 All Regions

Alternative 9 would require the repromulgation of the currently vacated 2008 Stream Buffer Zone rule. This Alternative would require minimization of excess spoil generation, place limits on excess spoil fill capacity to match the anticipated amount of excess spoil to be generated, and prohibit mining activities in or within 100 feet of an intermittent or perennial stream unless the applicant demonstrates and the regulatory authority finds that avoidance is not reasonably possible. The model mines analysis indicates that the impacts of Alternative 9 would not differ significantly from those of the No Action Alternative because the Clean Water Act requirements and policies discussed in the Regulatory Impact Analysis for this rulemaking and the state AOC and excess spoil policies identified in Section 4.2.3.1 of this FEIS have effectively achieved implementation of this Alternative in Central Appalachia, which is the region in which the 2008 Stream Buffer Zone rule would have had its greatest impact if it had remained in effect. Therefore, if repromulgated, Alternative 9 would now have Negligible effects on socioeconomic resources evaluated in this FEIS.

Table 4.3-28 presents the overall impacts to socioeconomic resources across regions and Action Alternatives.

Table 4.3-28. Summary of Impacts of the Action Alternatives on Socioeconomics Compared to the No Action Alternative

Alternative	Appalachian Basin	Colorado Plateau	Gulf Coast	Illinois Basin	Northern Rocky Mountains and Great Plains	Northwest	Western Interior	National
Alternative 2	Major Adverse	Negligible	Negligible	Minor Adverse	Minor Adverse	Negligible	Negligible	Moderate Adverse
Alternative 3	Moderate Adverse	Negligible	Negligible	Minor Adverse	Minor Adverse	Negligible	Negligible	Minor Adverse
Alternative 4	Moderate Adverse	Negligible	Negligible	Minor Adverse	Minor Adverse	Negligible	Negligible	Minor Adverse
Alternative 5	Moderate Adverse	Negligible	Negligible	Negligible	Negligible	Negligible	Negligible	Minor Adverse
Alternative 6	Minor Adverse	Negligible	Negligible	Minor Adverse	Minor Adverse	Negligible	Negligible	Minor Adverse
Alternative 7	Moderate Adverse	Negligible	Negligible	Minor Adverse	Minor Adverse	Negligible	Negligible	Minor Adverse
Alternative 8 (Preferred)	Moderate Adverse	Negligible	Negligible	Minor Adverse	Minor Adverse	Negligible	Negligible	Minor Adverse
Alternative 9	Negligible	Negligible	Negligible	Negligible	Negligible	Negligible	Negligible	Negligible

4.3.1.10 Uncertainties and Limitations

There are a variety of uncertainties and limitations inherent in this analysis, which have been discussed in the text above and are summarized below:

- Current volatility in the coal market makes anticipating future coal industry employment difficult, and also makes anticipation of future coal severance tax collection more difficult to anticipate. Our analysis uses a conservative labor productivity assumption to reflect that labor productivity in the coal mining industry has decreased steadily in recent years, especially in the Appalachian Basin region. Specifically, to be conservative (i.e., more likely to overstate than understate impacts), the average labor productivity of the least productive mines in each region in 2015 that comprise at least 25 percent of total production in each region is used. This means that for a given change in future production, our forecast will anticipate more labor demand decreases than if the current average productivity for each region was used. However, if labor productivity continues to substantially decrease, effects on employment may be greater than those reported above.

- IMPLAN (and input-output models in general) provides a static set of results that does not account for technological shifts, price changes, sectoral growth, or other factors. As such, the coefficient for estimating compliance employment impacts, and labor income impacts are constant over the period of study. Changes to the factors listed above could change behavior and affect the long-term impacts of the Action Alternatives on employment gains associated with compliance.
- In the severance tax analysis, an attempt was made to test the accuracy of using reported tax rates to estimate actual severance tax revenue. Severance tax revenue estimates were compared with actual severance tax revenues by state to determine the accuracy of the reported tax rate. For states where revenue estimates differed from actual revenues by more than 10 percent, the tax rate used to forecast future revenues was calculated as revenues divided by production.

4.3.1.11 Impacts to coal-related taxes (other than coal severance taxes) are not quantified.

The amount of tax revenue received from these other coal-related taxes varies greatly by state. Additionally, the precise relationship between coal production and tax revenues varies by tax type, and impacts to the revenues collected from these taxes are difficult to gather for the large area covered by this rule, as these taxes often are collected at the county level and have varying reporting requirements depending on the state.

4.3.1.12 Potential Minimization and Mitigation Measures

Impacts to employment and associated income could be mitigated by initiating programs aimed at diversifying employment opportunities in areas that rely heavily on coal mining as a source of employment and income. Mine operators could also re-train current employees to fill positions that have been created by complying with the Action Alternatives (excluding Alternative 9). Impacts to state severance tax revenues could be offset by shifting to extraction of other taxed fuel sources within the United States, such as natural gas. Even if this entirely counterbalanced losses in revenue due to decreased coal production, however, a shift to substitute fuel sources would likely affect the state-by-state distribution of tax revenue collected from extractive industries. Thus, a shift to substitute fuel sources would not necessarily mitigate effects within the same locality or region. OSMRE is also authorized to provide Small Operator Assistance Program (SOAP) funding to small coal mine operators (30 U.S.C. § 1257(c)). SOAP grants can provide financial assistance to mine operators in obtaining the scientific and technical information required to apply for a coal mining permit. This program has the potential to help minimize the burden of the costs of compliance with the Action Alternatives on small mine operators, perhaps decreasing potential employment impacts of the Action Alternatives.

4.3.2 Land Use, Utilities, Infrastructure, Visual Resources, and Noise

This section considers the potential effects of the Alternatives on changes in land use, utilities, infrastructure, visual resources, and noise. Recreation is treated separately in Section 4.3.3.

Chapter 3 describes general characteristics of the coal regions in relation to land use, utilities, infrastructure, visual resources, and noise at the regional level. This section of Chapter 4 analyzes how these resources are affected by the No Action Alternative and by the Action Alternatives under consideration for the SPR. Various elements of the Action Alternatives may indirectly affect aspects of these topics in the coal mining regions, particularly to the extent that this rule proposed action affects coal production in a particular region.

The discussion is organized as follows:

- It first describes the existing regulatory environment to assist the reader in understanding the impacts of the No Action Alternative on land use, utilities, infrastructure, visual resources, and noise.
- Second, the discussion identifies the aspects of these topics that are most likely to be affected by implementation of the Action Alternatives and the rationale for these findings.
- It then describes the method for assessing the expected magnitude of impact of the Action Alternatives on these resources.
- Next, the results of the quantitative analysis are presented, along with additional qualitative evaluation of other beneficial impacts.
- The section concludes with a summary of the expected effects of the Action Alternatives, characterizing the impacts by coal region and Alternative.

4.3.2.1 Effects of the Current Regulatory Environment (the No Action Alternative)

Section 3.7 characterizes land use, Section 3.11 characterizes visual resources and noise, and Section 3.12 characterizes utilities and infrastructure in each coal region. This section briefly discusses this information in the context of the No Action Alternative.

4.3.2.1.1 Land Use

Section 515(b)(2) of SMCRA requires the mining operation to restore affected lands to a condition capable of supporting the uses they were capable of supporting prior to mining, or to a higher or better use if certain criteria are met. 30 U.S.C. 1265(b)(2). The implementing regulations are located at 30 CFR 780.23, 784.15, 816.133, and 817.133.

4.3.2.1.2 Postmining Land Use

Paragraphs (a)(2) through (a)(4) of section 508 of SMCRA provide that each reclamation plan submitted as part of a permit application must include a statement of the condition of the land prior to any mining. As implemented through the regulations at 30 CFR 780.23, the application must describe the existing conditions and capabilities of the land under high levels of management. The reclamation plan also must include detailed descriptions of any proposed alternative uses and how they relate to existing land use policies and plans, and must be supported by comments from the surface owner of the permit area.

Section 515(b)(2) of SMCRA (30 U.S.C. § 1265(b)(2)) requires that all surface coal mining and reclamation operations:

Restore the land affected to a condition capable of supporting the uses which it was capable of supporting prior to any mining, or higher or better uses of which there is reasonable likelihood, so long as such use or uses do not present any actual or probable hazard to public health or safety or pose any actual or probable threat of water diminution or pollution, and the permit applicants' declared proposed land use following reclamation is not deemed to be impractical or unreasonable, inconsistent with applicable land use policies and plans, involves unreasonable delay in implementation, or violates federal, state, or local law.

The regulations at 30 CFR 816.133 and 817.133 essentially restate the statutory provisions and add language defining how the premining land uses must be determined; i.e., the premining land uses to which the postmining land use is compared must be those uses that the land previously supported if the land has not been previously mined and has been properly managed. For previously mined land that has not been reclaimed, the premining land use must be the land use that existed before any mining. If the previously mined land cannot be reclaimed to the land use that existed before any mining, the postmining land use must be the highest and best use that can be achieved, that is compatible with surrounding areas, and that does not require the disturbance of areas previously unaffected by mining.

In addition, the regulations at 30 CFR 701.5 define land uses as "specific uses or management-related activities, rather than the vegetation or cover of the land. Land uses may be identified in combination when joint or seasonal uses occur and may include land used for support facilities that are an integral part of the use." The regulations also define "higher or better uses" as "postmining land uses that have a higher economic value or nonmonetary benefit to the landowner or the community than the premining land uses."

If an alternative postmining land use is proposed, the application must contain the information required for approval of that use pursuant to 30 CFR 816.133(c) or 817.133(c), including demonstrations that the proposed use is achievable in a reasonable amount of time, that it would not present any public health or water pollution concerns, that it would be otherwise consistent with applicable land use policies and laws at the federal, state or local level.

4.3.2.1.3 Utilities and Infrastructure

Under the No Action Alternative, the existing SMCRA regulatory program provides a number of provisions intended to protect utilities and infrastructure, including features such as public roads, railroads, water and sewage lines, wells (oil, gas, and water), pipelines (oil, gas, and coal slurry), electric and telephone lines, and water supplies (drinking, domestic, or residential)(30 CFR 816.180 and 817.180).

In enacting SMCRA in 1977, Congress specifically mandated that, except under limited circumstances, surface coal mining operations may not be conducted within 100 feet, measured horizontally, of the outside right-of-way of any public road (30 U.S.C. § 1272(e)(4)). The exceptions to this prohibition are described at 30 CFR 761.14. These regulations allow an exception for circumstances where a mine access or haul road joins a public road, lands where an entity can show that it has "valid existing rights" as set forth in 30 CFR 761.16, or where the lands are associated with an operation that was existing prior to the road. Otherwise, regulatory authorities may only approve operations that would propose to relocate or close a public road to accommodate surface coal mining operations after providing for public notice and comment, and making a finding that the interests of the public and affected landowners would be protected. 30 CFR 761.14(c).

Under 30 CFR 816.180 and 817.180, all coal mining operations must be conducted in a manner that minimizes damage, destruction, or disruption of services provided by oil, gas, and water wells; oil, gas, and coal-slurry pipelines; railroads; electric and telephone lines; and water and sewage lines that pass over, under, or through the permit area, unless otherwise approved by the owner of those facilities and the regulatory authority. These regulations do not apply to the area located above underground mining activities if that area is not included within the permit area.

Under 30 CFR 816.62 and 817.62, the owner of any dwelling or structure (including pipelines, cables, transmission lines, and cisterns, wells, and other water systems) located within a half-mile radius of the permit area may request a preblasting survey of surface conditions, which the operator must complete before the initiation of blasting.

Transportation capacity issues are outside the regulatory reach of SMCRA, other than the public road requirements discussed above. For purposes of this FEIS, Section 3.12 provides an overview of each region's transportation methods and also assesses the potential future need for infrastructure expansion.

4.3.2.1.4 Visual Resources

The visual quality of areas surrounding coal mining is considered as a resource in this discussion because the visual appeal of surroundings affects the public's quality of life and how people feel about the area in which they live and work, and where they choose to recreate. The analysis described in the following sections assumes that the public would prefer that natural premining conditions be reproduced during reclamation. The analysis takes into account the extent to which reclamation using landforming principles can create greater opportunities to restore the site to its approximate premining condition and decrease adverse impacts on visual resources. The visual impacts that occur during mining are an understood consequence of the activity that the surrounding community weighs in comparison to the benefits of mining to the local economy. Neither SMCRA nor its implementing regulations specifically require the permit applicant to address the visual impacts of proposed operations.

During the active mining process, alterations to the existing vegetation and topography are often visually dramatic. Earthen materials overlying the coal are excavated and moved to various locations around the mine site. Vegetation is removed and portions of the mine site may remain without vegetation for long periods of time.

Once mining is completed, surface mining companies are, with limited exceptions, required to restore the mine site to its AOC via backfilling and regrading. However, in some (steep-slope) terrain, the increase in volume of spoil relative to solid rock results in excess spoil fills outside the mined area, even when the mined area is returned to AOC. In addition, AOC variances are available that can result in altered postmining topography on the mined areas, as well as excess spoil fills outside the mined areas. Access roads and drainage control ponds may be approved as permanent features, altering the visual resources of an area. With the exception of mined areas returned to AOC, all of these features, if present, change the landscape in ways not consistent with the natural topography.

Use of non-native species is often a consequence of conversion of land to new postmining land uses; for example, the conversion of forest to agricultural land and forested areas to grassland grazing areas. The converted site looks visually different and is different in terms of recreational opportunities, land use, and wildlife habitat value.

Visual resource impacts are often considered during preparation of NEPA analysis for mining on federal lands or for mining of coal for which the U.S. holds the mineral rights. The Secretary of the Department of the Interior is responsible for authorizing the mining plan for federal coal leased by the U.S. Bureau of Land Management (U.S. BLM). The requirement for an approved mining plan is set forth under the federal Mineral Leasing Act, which states that before any entity can take action on a federal leasehold that “might cause a significant disturbance to the environment,” an operation and reclamation plan must be submitted to the Secretary of the Interior for approval (30 U.S.C. § 207(c)). OSMRE is charged to “prepare and submit to the Secretary a decision document recommending approval, disapproval, or conditional approval of the mining plan” (30 CFR 746.13).

Surface mining results in greatly disturbed landscapes. Reclamation of these landscapes is achieved with varying degrees of success with regard to previous visual character. Regional variations in rainfall and topography require different approaches to reclamation, and affect the amount of effort required to achieve successful reclamation and restoration of the premining appearance of the site. How well the land is returned to the premining condition depends on the regulatory authority’s AOC requirements, as well as regional and site-specific conditions.

Impacts to visual resources do occur under the No Action Alternative; they are not completely avoidable unless mining is precluded altogether.

4.3.2.1.5 Noise

Mining activities cause noise in and around the mine site. Surface coal mining operations often employ large earth-moving vehicles and other machinery which can produce noise during the mine operation. Surface mining, which relies on blasting to remove overburden, generally creates more noise than underground mining. Underground mining operations often have large ventilation systems that produce noise during mine operation. Depending on the location of the mining activity and its proximity to noise sensitive areas, mining related noise can interfere with human enjoyment of areas immediately surrounding the mining activity.

Blasting operations are sporadic events, but they are of particular concern because of potentially damaging low-frequency noise and pressure waves. Therefore, the regulations require careful planning, control, and monitoring of blasting events to ensure that blasting occurs under safe conditions. Setback requirements from dwellings, public buildings, schools, and churches reduce noise impacts to sensitive receptors under the No Action Alternative, as do existing requirements to conduct blasting between sunrise and sunset unless nighttime blasting is approved by the regulatory authority upon a determination that the public will be protected from adverse noise and other impacts. See 30 CFR 816.61 through 816.68 and 817.61 through 817.68.

As noted above, underground mines involve a number of noise-making processes and equipment, most of which produce noise solely underground. However, surface noise from underground mining does result from the use of large intake and exhaust fans that vent methane from underground mine operations, and from conveyor belts or trains, trucks, and dozers used to transport coal and coal mine waste.

The primary responsibility for addressing construction noise, noise from power equipment operated by individuals, and unmuffled industrial noise penetrating residential areas, rests with states and local governments. Thousands of U.S. cities have implemented noise ordinances that give noise control officers and police the power to investigate noise complaints and enforcement power to abate the offending noise source through shutdowns and fines. A typical noise ordinance sets forth clear definitions of acoustic nomenclature and defines categories of noise generation; then numerical standards are established so that enforcement personnel can take the necessary steps of warnings, fines, or other municipal police action to rectify unacceptable noise generation. Under the No Action Alternative, coal mining would continue to produce noise as described above. Noise from coal mining may then affect surrounding communities and wildlife. As seen in Table 4.3-29 below, there are no additional measures proposed under any Alternative that would affect the production of noise in comparison to the No Action Alternative to a measurable degree.

4.3.2.2 Action Alternatives and Potential Effects on Land Use, Utilities, Infrastructure, Visual Resources, and Noise

Various elements of the Alternatives may affect land use, utilities, infrastructure, visual resources, and/or noise associated with areas disturbed by mining activities. Each of the rule elements is discussed below. Table 4.3-29 summarizes the effects of various elements of the Action Alternatives on these resources.

Table 4.3-29. Action Alternatives Elements and Potential Effects on Land Use, Utilities, Infrastructure, Visual Resources, and Noise in Coal Mining Regions

Action Alternatives Element	Land Use	Utilities	Infrastructure	Visual Resources	Noise	Indirect Impacts Expected
Baseline Data Collection and Analysis						■
Monitoring During Mining and Reclamation						■
Definition of Material Damage to the Hydrologic Balance						■
Evaluation Thresholds						■
Stream Definitions						■
Mining Through Streams	■			■		
Activities In or Near Streams Including Excess Spoil and Coal Refuse	■			■		
AOC Variances	■			■		
Surface Configuration	■			■		
Revegetation, Topsoil Management, and Reforestation	■			■		
Fish and Wildlife Protection and Enhancement	■			■		

Note: No elements are expected to change noise conditions, utilities, or infrastructure. Impacts to these resources are related changes in coal production that could result from the Action Alternatives.

4.3.2.2.1 Protection of the Hydrologic Balance

4.3.2.2.1.1 Baseline Data Collection and Analysis

The elements of the Action Alternatives associated with baseline data collection and analysis serve to direct water sampling procedures. Under the No Action Alternative, the current requirements for the baseline data that must be collected and analyzed will continue, and no impact on the current trends of coal mining, land use, utilities, infrastructure, visual resources, or noise are expected.

The rule elements associated with baseline data collection and analysis serve to specify water sampling and analysis procedures.

- Under the No Action Alternative (Alternative 1) some requirements for baseline data collection and analysis exist, as described in Chapter 2. Data characterizing premining conditions allow mine operators and regulators to identify the incremental effects of the mining activity on monitored water quality parameters.
- The Action Alternatives (excluding Alternative 9) standardize the sampling protocol and increase the assessment and monitoring activities for baseline data collection and analysis, as described in

Chapter 2. These changes are not expected to directly affect land use activities but may lead to indirect effects on land uses to the extent that they promote improved water quality in the region.

- The requirements of Alternative 9 with respect to this element are the same as the No Action Alternative and, as such, their effects on land use are the same as the No Action Alternative.

4.3.2.2.1.2 Monitoring During Mining and Reclamation

As with the collection of baseline data described above, improved monitoring would not alter land use, utilities, infrastructure, visual resources, and noise resources directly. However, the Action Alternatives establish timeframes for data monitoring and review and include additional metrics to be collected. Such changes may, in some cases, have an indirect benefit to land use, utilities, infrastructure, visual resources, and noise resources if planned mining operations are changed. For instance, baseline data collection may highlight a stream segment that contains rock that contains selenium before mining commences. This area could be avoided for mining purposes, reducing the likelihood of release of the pollutant into surface waters, thus minimizing the potential for impacts, particularly with regard to land use.

While the phrase "material damage to the hydrologic balance outside the permit area" appears in SMCRA and implementing regulations, no federal definition currently exists. Thus, under the No Action Alternative, although surface coal mining operations are required to be designed and performed in a way that prevents material damage to the hydrologic balance outside the permit area, the regulation lacks specificity as to what constitutes material damage to the hydrologic balance outside the permit area. This has led to difficulties in the enforcement of this requirement (Reis, 2010). Without a formal definition of material damage to the hydrologic balance outside the permit area, it may not be possible to prevent its occurrence through regulation and enforcement. Adding a definition would not in and of itself be expected to alter the subject resources; however, its inclusion in some of the Action Alternatives may have indirect effects related to the likelihood of avoidance of adverse impacts to land use.

4.3.2.2.1.3 Evaluation Threshold

Evaluation thresholds are standards set at lower levels than those for material damage to the hydrologic balance and are designed to act as a warning system to prevent material damage to the hydrologic balance from being reached. Under the No Action Alternative, because no formal definition of material damage to the hydrologic balance exists, no evaluation thresholds exist. Consequently, current coal mining impacts on land use, utilities, infrastructure, visual resources, and noise would be expected to continue. Evaluation thresholds associated with a definition of material damage to the hydrologic balance, as applied in some of the Action Alternatives should have no direct effect on land use, utilities, infrastructure, visual resources, or noise; however, their inclusion in the Action Alternatives may be expected to have indirect effects on coal production siting, which may affect land use.

4.3.2.2.2 Activities In or Near Streams

4.3.2.2.2.1 Stream Definitions

Stream definitions are central to the water quality protection objectives of the Action Alternatives. The No Action Alternative enumerates the elements used to define a general stream as well as an intermittent stream. Retention of the current stream definitions is anticipated to continue current mining effects on land use, utilities, infrastructure, visual resources, and noise. Changes in stream definitions associated with some of the Action Alternatives are expected to have an indirect effect on the respective resources.

4.3.2.2.2.2 Mining Through Streams

Restoration of streams using natural channel design techniques is currently required following coal mining activity, but no requirement to restore stream ecological function is presently in place. Natural channel design does not consider many biophysical factors that determine the stream's ability to support biological resources. In fact, evidence suggests that the natural channel design strategy may decrease biodiversity following restoration and which may continue to decrease over time (see review of Bernhardt and Palmer (2011) for additional information regarding adverse ecological impacts associated with natural channel design). For all Action Alternatives, specific performance standards would be required to guide stream restoration, such as the requirement to restore natural hydrologic form and biological function for intermittent and perennial streams and natural hydrologic form for ephemeral streams. Alternatives 2 and 7 explicitly prohibit all mining activities in or within 100 feet of a perennial stream and require that all perennial, intermittent, and ephemeral streams be restored to form. Alternatives 3, 4, 5, and 6 require restoration of the hydrologic form and ecological function of all intermittent and perennial streams and restoration of the form of ephemeral streams to the extent required by geomorphic reclamation. Alternative 8 (Preferred) requires restoration of both the hydrologic form and ecological function of intermittent and perennial streams and requires restoration of the hydrologic form of ephemeral streams. Alternative 9 requires stream restoration using natural channel design techniques. The requirements to limit mining through streams and restore streamside areas would have a beneficial effect on land use and visual resources which would vary by region and Alternative, depending on the extent of the requirements, the extent of mining activity, and any protective actions already anticipated to occur under the No Action.

4.3.2.2.2.3 Activities In or Near Streams, Including Excess Spoil and Coal Refuse

Under the No Action Alternative, mining activities in or within 100 feet of perennial or intermittent streams is prohibited unless the regulatory authority finds that the mining activities will not cause or contribute to the violation of state or federal water quality standards and will not adversely affect the quantity or quality or other environmental resources of the stream.

The Action Alternatives (excluding Alternative 9) increase the stringency of the requirements that guide mining activities near streams as well as the placement of excess spoil and refuse. The Action Alternatives (except Alternative 9) also add provisions for allowable fill construction techniques and increased monitoring during fill construction. To the extent that mining avoids areas near streams that otherwise would be affected by mining, benefits to those areas would be expected. Alternative 2 prohibits excess spoil in intermittent and perennial streams. Alternatives 3, 4, and 5 add requirements to mining activities within 100 feet of intermittent and perennial streams. Alternatives 6 and 8 (Preferred) include additional requirements: restoration of ecological function of perennial and intermittent streams; offset of long-term effects in same or adjacent drainage; prohibition of adverse effects to water quality or other environmental resources of the stream when mining activities occur within the buffer zone, but not the stream; and a 100 foot wide streamside vegetative corridor along all streams. Alternative 7 prohibits excess spoils in perennial streams. The requirements of Alternative 9 match those of the No Action Alternative. Overall, land use would benefit from prevention of stream degradation because water-dependent land uses would continue. Visual resources would benefit because healthy streams are visually appealing, which provide benefits to nearby populations and can be attractive for recreators.

4.3.2.2.3 Approximate Original Contour

4.3.2.2.3.1 AOC Variances

As discussed in Section 4.2.3.1, SMCRA and the existing regulations (the No Action Alternative) provide several exceptions to the requirement to restore mined land to AOC. Those exceptions include operations with thin or thick overburden, certain remining operations, mountaintop removal mining operations, and steep-slope mining operations. The latter two exceptions apply only when the mountaintop removal mining operation or the AOC variance for a steep-slope mining operation will facilitate one or more specified postmining land uses and certain other requirements are met. These two variances apply only to operations consisting primarily of steep slopes (slopes in excess of 20 degrees), a situation that occurs almost exclusively in Central Appalachia.

Under the No Action Alternative, the most visible impact of AOC variances would be the continued limited creation of flat or gently rolling terrain in areas that previously contained primarily steep slopes. More moderate slopes also may reduce surface runoff because of higher infiltration rates. Alternative 2 would prohibit all AOC variances and would likely require amendment of SMCRA. Alternatives 3, 4, 5, and 8 (Preferred) likely would result in the approval of fewer operations with AOC variances. Therefore, Alternatives 2, 3, 4, 5, and 8 (Preferred) should result in fewer permanent visual effects than would be expected under the No Action Alternative. Alternatives 6, 7, and 9 are similar to the No Action Alternative in terms of AOC variances and, thus, would have similar impacts.

4.3.2.2.3.2 Surface Configuration

As discussed in Section 4.2.3.1, SMCRA requires that the permittee backfill and grade the mined area to its AOC, which means a surface configuration that closely resembles the premining surface configuration and that blends into and complements the drainage pattern of the surrounding terrain. The existing regulations (the No Action Alternative) contain similar provisions. Alternatives 6, 8 (Preferred), and 9 would not alter the existing regulations with respect to surface configuration requirements.

Alternatives 2, 3, and 4 would require that almost all surface mining operations use digital terrain analysis techniques to determine whether AOC restoration requirements have been met. Alternatives 5 and 7 would require use of digital terrain analysis techniques for a smaller subset of operations; e.g., operations that dispose of excess spoil or coal mine waste.

Alternatives 2, 3, and 4 would require use of landforming principles as part of backfilling and grading to prevent the creation of uniform slopes vulnerable to erosion and to promote restoration of topographical features that will re-create microclimates and ecological niches present prior to mining. However, Alternative 3 would not apply those principles to excess spoil fills.

Alternatives 2 and 4 would require that the thickness of backfilled material at any point in the backfilled area not differ from the combined premining thickness of the coal seam and overburden strata at that point by more than ± 20 percent.

Alternatives 2, 3, and 4 would have the greatest impact on topography because they are most likely to ensure that the final surface configuration and landscape features more closely match the premining configuration and landscape features. The greatest impact would occur in regions highly variable premining topography, such as mountainous terrain. Alternatives 5 and 7 would have a lesser impact on topography than Alternatives 2, 3, and 4, but a greater impact than the No Action Alternative. Alternatives 6, 8, and 9 would not differ in impact from the No Action Alternative.

4.3.2.2.4 Postmining Land Use and Enhancement

4.3.2.2.4.1 Revegetation, Topsoil Management, and Reforestation

Postmining land cover is influenced by the revegetation, topsoil management, and reforestation elements of the Alternatives. Under the No Action Alternative, reforestation is not required, although the establishment of vegetative cover is required. Species native to the area are emphasized for revegetation although introduced species are permitted. Provided the mining operator demonstrates compliance with the regulations, selected overburden materials may be used in place of the topsoil removed from the disturbed area. Finally, use of all available organic materials available within the disturbed areas is not required.

Some beneficial effects on revegetation, topsoil management, and reforestation are anticipated under Action Alternatives 2, 3, 4, 5, 7, and 8 (Preferred). Specifically, the revegetation of reclaimed lands must be completed using only native species unless specifically required to achieve the approved postmining land use; the use of overburden materials as a replacement for, or as a supplement to, topsoil requires greater justification; available organic materials must be incorporated into the revegetation process; and reforestation of previously forested areas is required. In addition, soil handling and redistribution must be done in a manner that limits compaction and provides optimal root development to support the approved revegetation plan and postmining land use. These changes serve primarily to return the postmining land to a native forest ecosystem as quickly as possible. By enhancing the return of the native forest ecosystem expeditiously, this element would be expected to beneficially impact land use and visual resources; it would not be expected to impact infrastructure or noise resources. Alternatives 6 and 9 keep the same requirements as under the No Action Alternative and no change is anticipated for revegetation, topsoil management, and reforestation; hence, no impacts on land use, utilities, infrastructure, visual resources, or noise are expected.

4.3.2.2.4.2 Fish and Wildlife Protection and Enhancement

The Alternatives contain some elements designed to protect and enhance the fauna inhabiting the mine site and adjacent areas, including downstream aquatic life. Under the No Action Alternative and Alternative 9, quantifiable enforcement guidance is lacking (with perhaps the exception of the prohibition of surface mining activity likely to jeopardize endangered or threatened species). The other Alternatives provide qualitative goals, including the enhancement of fish and wildlife resources whenever long term losses result from the mining operations and the avoidance of disturbances to wetlands and streamside vegetation. To the extent that this element discourages disturbance of particular areas of high habitat value, land use and visual resources may be less affected.

4.3.2.3 Assessment of Impacts to Land Use, Utilities, Infrastructure, Visual Resources, and Noise

A qualitative assessment of impacts stemming from the Alternatives is based on the premise that mining itself constitutes a disturbance to land use, utilities, infrastructure, visual resources, and noise. Changes in the quantity of mining will change impacts to land use, utilities, infrastructure, visual resources, and noise. The No Action Alternative, as it leaves current regulations in place, is expected to continue trends of coal mining impacts on these resources. Table 4.2-23 in the Topography, Geology, and Soils section of this FEIS presents coal production projections across Alternatives and regions between the years 2020 and 2040. In sum, the following effects are expected:

- There is a decrease in coal production projections for Alternative 2 in the Appalachian and Illinois Basin regions. For all other regions, Alternative 2 is expected to have negligible effects on future coal production;
- Alternatives 3, 4, 5, 7, and 8 (Preferred) are similar to Alternative 2 in their impacts across regions, but with smaller decreases in coal production;
- In the Appalachian Basin under Alternative 2, there would be a minor shift in production from surface mining to underground mining; and
- Alternatives 6 and 9 have negligible effects on coal production across all regions, and as such, would not appreciably affect land use, utilities, infrastructure, visual resources, or noise when compared with the No Action Alternative.

Changes in the area disturbed by coal mining are central to characterizing effects on land use, utilities, infrastructure, visual resources, and noise. The analysis quantifies these changes based on estimated rates of land disturbance per million tons of coal mined. As described in Section 4.2.3, although the techniques applied in the Action Alternatives may have other beneficial environmental impacts, only Appalachian Basin mines exhibit decreased area disturbed per ton mined under the Alternatives. Other regions showed no significant changes in this metric across the Action Alternatives, relative to the No Action Alternative. The general finding is that only Alternative 2 will result in less land disturbed per million tons of coal mined, and that will occur only in Central Appalachia.

4.3.2.3.1 Land Use

The lack of data on specific areas that will be mined in the future makes a quantitative assessment of changes in land use resulting from the Action Alternatives difficult. Under the No Action Alternative, coal mining operations are a short-term use of the land, which must be restored to a condition capable of supporting the uses which it was capable of supporting prior to any mining or to higher or better uses of which there is a reasonably likelihood. (30 U.S.C. § 1265(b)(2)).

Land use trends are dependent on a number of factors, including prevailing macroeconomic conditions and existing and planned land use regulations and initiatives at the federal, state, and local levels. The Action Alternatives have the potential to reduce impacts to land use by reducing land disturbance from mining activities. However, in some cases, if mining activity is shifted among coal regions, impacts on land use would also be shifted rather than reduced.

The impact of changes from the Action Alternatives on land use also depends on the impacts on the type of mining. If an Action Alternative results in a shift from surface to underground mining, a smaller portion of surface land would be affected, so any change in land use on the disturbed area would affect a smaller site.

Decisions to construct residential land use developments could be affected by the Action Alternatives. Development of surface coal production cannot occur in existing residential areas or other prohibited areas unless homeowners agree to waive the minimum set back distances. Future development plans, however, may suffer if visual noise and disturbances exist from adjacent mining. To the extent that surface mining shifts to underground mining, surface land in a region may benefit from the improved viewscape and/or reduced ambient noise. Conversely, fortified requirements for restoring AOC (as in Alternative 2) may hamper future development by limiting the extent to which mining operations can prepare postmining landscapes that facilitate development.

The changes proposed in the Action Alternatives (excluding Alternative 9) would improve compliance with the conditions for approval of higher or better uses under section 515(b)(2) of SMCRA (30 U.S.C. § 1265(b)(2)) and the AOC restoration requirements of section 515(b)(3) of SMCRA (30 U.S.C. § 1265(b)(3)). Specifically, all of the Action Alternatives (except Alternative 9) would require that the applicant document a reasonable likelihood of achieving the higher or better use through submission of real estate and construction contracts, plans for installation of any necessary infrastructure, procurement of any necessary zoning approvals, landowner commitments, economic forecasts, and studies by land use planning agencies, as applicable.

An assessment of impacts stemming from the Action Alternatives was conducted for land cover and land use using Geographic Information Systems (GIS) land cover data.[45] Specifically, the study area for analysis, which includes areas that produced coal in the past five years and which fall within potentially mineable coal reserves (see Section 3.7.2), was overlaid with National Land Cover Dataset data (2011). From these data, the total percent of major land cover types across the seven coal regions in the study area were determined.[46] Table 4.3-30 provides a brief summary of land cover types across coal regions in the study area.

[45] This analysis also borrows from the same dataset and method as the analysis done in 4.2.2 Biological Resources. USGS's National Land Cover Dataset (2011) was used for the land cover analysis.

[46] Section 3.7 and Section 4.2.2 discuss the variations in land cover among the seven different regions outlined in the study. Coal-producing counties were identified from the MSHA Coal Production 2012 dataset (2008-2012).

Table 4.3-30. Land Cover Types by Coal Region in Study Area

Coal Region	Forest	Grass	Shrub	Cropland	Other[1]	Total
Appalachian Basin	91%	0.1%	0.0%	8%	0.6%	100%
Colorado Plateau	39%	6%	52%	1%	1%	100%
Gulf Coast	41%	41%	8%	9%	0.6%	100%
Illinois Basin	12%	0.2%	0.4%	86%	1%	100%
Northern Rocky Mountains	3%	49%	31%	17%	0.4%	100%
Northwest	41%	28%	21%	4%	5%	100%
Western Interior	18%	7%	0.3%	73%	2%	100%

Source: USGS, 2011c.
[1] The "Other" category includes the following categories from the original land use dataset: "Consolidated Rock Sparse Vegetation", "Unconsolidated Material Sparse Vegetation (old burnt or other disturbance)", "Urban and Built-up", "Water bodies", and "Wetlands". Areas unlikely to be mined, such as urban areas, national parks, and lakes and ponds were excluded from the study area; however, the land use data comes from a different dataset than the datasets used for this exclusion process, and there is therefore some residual error generated by this process such that these calculations show some area under these categories.

Land cover indicates the vegetative cover found in any particular area and often indicates the land use of that particular area. Unless clearly beneficial, to the degree that coal mining alters the premining land use, it is assumed to have an adverse effect. Insofar as the Action Alternatives improve mine site restoration, they are assumed to reduce the adverse land use impacts on agriculture and residential and commercial development. If Action Alternatives reduce mining or shift mining underground, they are assumed to reduce the adverse impacts of mining on land use.

4.3.2.3.2 Utilities

Among utilities, the Action Alternatives are expected to primarily affect electric utilities.[47] Since coal is used throughout the U.S. in electricity generation, analysis of the Action Alternatives requires a national perspective. The U.S. Energy Information Administration (U.S. EIA) provides monthly electricity production and price data by generation source. The contribution of coal to electricity generation varies across regions and states. Section 3.12 outlines the relative dependence of each coal region on coal as an energy source. As described, states vary in terms of dependence on coal from as little as zero percent in Rhode Island and Vermont to as much as 95.3 percent in West Virginia (U.S. EIA, 2013f). Similarly, electricity prices within the 48 contiguous states vary from a low of $7.44 per kilowatt hour (kWh) in Louisiana to a high of $17.16 per kWh in Connecticut (U.S. EIA, 2016c). If states that are heavily dependent on coal for electricity production lose supply due to the implementation of the Action Alternatives, costs per kilowatt hour may rise. Cost effects, however, would also be influenced by other market factors, such as the ability to substitute competitively priced alternative electricity generation sources and coal production changes amongst the regions. However, in the context of the total coal supply and demand for utilities, the forecasted changes in production are expected to have a minimal measurable impact on utilities across the Action Alternatives.

Some of the Action Alternatives would affect utilities if there is a change to the cost or availability of coal in a particular region. For instance, if states dependent on coal for electricity generation face decreased

[47] Improvements in water quality may benefit public drinking water suppliers by reducing pollutant levels and therefore costs of water treatment. This is discussed further in Section 4.2.1 and 4.3.4.

coal supply due to the Action Alternatives, electricity costs per kilowatt hour may rise. In addition to the influence of coal availability, electricity costs would also be influenced by other market factors such as the availability of substitute electricity sources and trends in consumer demand and conservation.

4.3.2.3.3 Infrastructure

Transportation infrastructure projects in certain regions may benefit from various elements of the Action Alternatives. As discussed earlier, effects of the Action Alternatives on transportation infrastructure are expected to follow the trends associated with changes to coal production. If mining operations shift regionally because of the Action Alternatives, new infrastructure development may be necessary in some regions. For example, as outlined in Section 3.12, if production increases in the Northern Rocky Mountains and Great Plains region, the region would likely require investment in railroad projects to transport additional reserves to market without delay from congestion.[48] Currently, areas such as the Northern and Central Appalachian areas are estimated to be operating at near to full capacity, and would require rail and road infrastructure development in the event more mining occurs. The Illinois Basin would also require improvements in rail capacity in the event mining increases within the region. However, in any of these regions, roads and railways may suffer less wear in the event that Action Alternatives limit or shift coal production away from the area as shown in Table 4.2-23.

4.3.2.3.4 Visual Resources

Effects on visual resources are influenced by the extent of mining, the prevalence of surface mining, and postmining reclamation. Alternatives 2, 3, 4, 5, 7, and 8 (Preferred) require reforestation of previously forested land and decrease postmining impacts to visual resources. Alternatives 2, 3, 4, 5, and 8 (Preferred) require more stringent reforming of AOC than Alternatives 6, 7, or 9, leading to a greater reduction in postmining impacts to visual resources relative to those Alternatives. Overall changes in the volume of regional coal extraction and the ratio of surface to underground mining, as shown in Table 4.2-23, also influence visual resources.

4.3.2.3.5 Noise

Short-term impacts from noise are assumed to be directly related to the total volume of coal mining (Section 4.1 describes forecasted production under the Alternatives). As such, noise impacts would likely decrease under all the Action Alternatives, but to varying degrees. The greatest noise reductions would likely be realized under Alternative 2, followed by Alternatives 3 and 7. In addition, Alternative 2 involves shifts from surface to underground mining in the Appalachian Basin region; this change could also reduce noise impacts.

4.3.2.4 Summary of Effects

As discussed in Section 4.0.3, this section considers the potential effects of the Alternatives on land use, utilities, infrastructure, visual resources, and noise. Some impacts of the Alternatives on these resources would be confined to the mining period (short-term), and other impacts would be expected to extend beyond the period of active mining (long-term). A number of impacts on these resources are anticipated to be beneficial (e.g., a reduction in the amount of surface coal mined may decrease the total area of

[48] See Section 3.12 for a full discussion of current and future projections of transportation infrastructure.

affected land use and reduce adverse impacts on visual resources, infrastructure, and noise). Other impacts are anticipated to be neutral or negligible (e.g., because increased utility prices are expected to be passed through to consumers, impacts to utilities for all Action Alternatives are classified as Negligible.) Determinations of the intensity of impacts on these resources considered the impacts of the Action Alternatives on each of these resources. Specifically, determinations were made using the following analytical categories:

- Negligible: Minimal measurable impacts (adverse or beneficial) are expected; or short term effects to a small geographic area, community or economy.
- Minor Beneficial: The action could reduce land disturbances in localized areas. The impacts could affect decisions to construct residential, commercial, and agricultural developments. The action could improve public services or utilities, but the impact would be localized and within operational capacities. There could be an improvement in the viewshed that is readily apparent. The action could decrease noise, but its benefit to the soundscape would be localized and unlikely to affect current user activities.
- Moderate Beneficial: The action could reduce land disturbances in local and adjacent areas. The impacts could affect decisions to construct residential, commercial, and agricultural developments in surrounding areas. The action could improve public services or utilities in local and adjacent areas. Short service interruptions to roadway and railroad traffic could be reduced. There could be an improvement in the viewshed that is readily apparent. The changes would not markedly improve the viewscape, but could enhance current user activities or experiences. The action could decrease noise and the benefit could improve the soundscape in local and adjacent areas. User activities could be enhanced.
- Major Beneficial: The action could reduce land disturbances over widespread areas. The impacts could affect decisions to construct residential, commercial, and agricultural developments in the region. The action could improve public services or utilities over a widespread area resulting in an increase of certain services or necessary utilities. Extensive service disruptions to roadways or railroad traffic could be reduced. There could be improvements to characteristic views of the region, which could enhance current user activities or experiences. The action could decrease noise and improve the soundscape over widespread areas. Noise levels could enhance user activities.

As noted throughout, the No Action Alternative, which leaves current regulations unchanged, is expected to continue current trends of coal mining impacts on the resources discussed in this section. Also, in the context of the total coal supply and demand for utilities, the forecasted changes in production due to the Action Alternatives are expected to have a minimal impact, resulting in an average change in electricity costs ranging from a 0.06 percent increase under Alternative 2 to a zero percent change under Alternative 9, nationally. However, because increased utility prices are expected to be passed through to consumers, impacts to utilities for all Action Alternatives are classified as Negligible. The analyses of the impacts of the No Action Alternative are presented in Sections 4.3.2.1 through 4.3.2.4.

Alternative 2 is anticipated to result in Minor Beneficial results to land use, utilities, infrastructure, visual resources, and noise at the national scale when compared to the No Action Alternative. Other Alternatives are anticipated to result in Negligible impacts at the national scale.

At a regional scale, Moderate Beneficial impacts to land use, utilities, infrastructure, visual resources, and noise are anticipated in the Appalachian Basin under Alternatives 2, 3, 4, 5, 7, and 8 (Preferred). Effects on land use, utilities, infrastructure, visual resources, and noise are anticipated to be Minor Beneficial or Negligible in other regions when compared to the No Action Alternative.

4.3.2.4.1 Alternative 1 (No Action Alternative)

Under the No Action Alternative, no further regulations or corrective measures in addition to those already in place would be implemented. Therefore, ongoing trends in land use, utilities, infrastructure, visual resources, and noise would continue. The annual quantity of coal demanded and associated production is anticipated to be approximately 10 percent lower in 2040 than in 2020 without implementation of the Alternatives (i.e., under the No Action Alternative). This reduction in production would reduce adverse impacts of ongoing coal mining activities on land uses under the No Action Alternative.

Reduced coal production would reduce adverse impacts to land use, reduce demands on utilities, and infrastructure, reduce adverse impacts to visual resources, and reduce noise in coal mining regions under the No Action Alternative.

In concert with the above, efforts to improve land use, utilities, infrastructure, visual resources, and noise conditions under the EPA Noise Control Regulations, the Emergency Watershed Protection (EWP), the Forest Service Manual (FSM), and regional growth and development trends, as well as regional, state, local mine reclamation efforts, may continue to improve land use conditions in localized areas under the No Action Alternative.

4.3.2.4.2 Alternative 2

4.3.2.4.2.1 Appalachian Basin Region

Analysis suggests that this Alternative would cause a slight decrease in total coal production for this region, coupled with a minor shift towards underground mining. Such changes would decrease the total area of affected land use and reduce adverse impacts on visual resources, infrastructure, and noise. This would be largely due to a reduction in the area disturbed per million tons of coal mined. Improved reforestation under Alternative 2 would create beneficial impacts on land use and visual resources in areas that are disturbed, as would strengthening requirements to achieve AOC. Taken together, this Alternative is anticipated to have long–term, and medium scope beneficial impacts on land use, visual resources, and noise. It is therefore classified as having an overall Moderate Beneficial effect on land use, utilities, infrastructure, visual resources, and noise.

4.3.2.4.2.2 Colorado Plateau Region and Gulf Coast Region

The analysis for this Alternative shows minimal measurable impacts to the resources examined within these regions and therefore, Negligible impacts are anticipated.

4.3.2.4.2.3 Illinois Basin Region

Analysis indicates that this Alternative would slightly decrease total coal production in this region, thereby slightly decreasing the total area of affected land use, reducing infrastructure demands, and lessening adverse impacts on visual resources and noise. Therefore, this Alternative would likely have long term and small scope impacts and, thus, is classified as an overall Minor Beneficial effect on land use, utilities, infrastructure, visual resources, and noise.

4.3.2.4.2.4 Northern Rocky Mountains and Great Plains Region

Analysis indicates that this Alternative would slightly decrease total coal production in this region, thereby slightly decreasing the total area of affected land use, reducing infrastructure demands, and lessening adverse impacts on visual resources and noise. Therefore, this Alternative would likely have long term and small scope impacts, and, thus, is classified as an overall Minor Beneficial effect on land use, utilities, infrastructure, visual resources, and noise.

4.3.2.4.2.5 Northwest Region and Western Interior Region

The analysis for this Alternative shows minimal measurable impacts to the resources examined within these regions and therefore, Negligible impacts are anticipated.

4.3.2.4.3 Alternative 3

4.3.2.4.3.1 Appalachian Basin Region

Analysis suggests that this Alternative would cause a slight decrease in total coal production for this region. Such changes would decrease the total area of affected land use, reduce infrastructure demands, and lessen adverse impacts on visual resources and noise. In addition, the area disturbed per million tons of coal mined would decrease. Improved reforestation under Alternative 3 would create beneficial impacts on land use and visual resources. Taken together, this Alternative is anticipated to have a long term and medium scope impact and, thus, is classified as an overall Moderate Beneficial effect on land use, utilities, infrastructure, visual resources, and noise.

4.3.2.4.3.2 Colorado Plateau Region and Gulf Coast Region

The analysis for this Alternative shows minimal measurable impacts to the resources examined within these regions and therefore, Negligible impacts are anticipated.

4.3.2.4.3.3 Illinois Basin Region

The analysis indicates that this Alternative would slightly decrease total coal production in this region, thereby slightly decreasing the total area of affected land use, reducing infrastructure demands, and lessening adverse impacts on visual resources and noise. Therefore, this Alternative would likely have long term and small scope impacts and, thus, is classified as an overall Minor Beneficial effect on land use, utilities, infrastructure, visual resources, and noise.

4.3.2.4.3.4 Northern Rocky Mountains and Great Plains Region, Northwest Region, Western Interior Region

The analysis for this Alternative shows minimal measurable impacts to the resources examined within these regions, and, therefore, Negligible impacts are anticipated.

4.3.2.4.4 Alternative 4

4.3.2.4.4.1 Appalachian Basin Region

Analysis suggests that this Alternative would cause a slight decrease in total coal production for this region, coupled with a minor shift towards underground mining. Such changes would decrease the total area of affected land use, reduce infrastructure demands, and lessen adverse impacts on visual resources and noise. In addition, the area disturbed per million tons of coal mined would decrease. Improved reforestation would create beneficial impacts on land use and visual resources. Taken together, this Alternative is anticipated to have a long term and medium scope impact and, thus, is classified as an overall Moderate Beneficial effect on land use, utilities, infrastructure, visual resources, and noise.

4.3.2.4.4.2 Colorado Plateau Region and Gulf Coast Region

The analysis for this Alternative shows minimal measurable impacts to the resources examined within these regions and therefore, Negligible impacts are anticipated.

4.3.2.4.4.3 Illinois Basin Region

Analysis indicates that this Alternative would slightly decrease total coal production in this region, thereby slightly decreasing the total area of affected land use, reducing infrastructure demands, and lessening adverse impacts on visual resources and noise. Therefore, this Alternative would likely have long term and small scope impacts, and, thus, is classified as an overall Minor Beneficial effect on land use, utilities, infrastructure, visual resources, and noise.

4.3.2.4.4.4 Northern Rocky Mountains and Great Plains Region, Northwest Region, Western Interior Region

The analysis for this Alternative shows minimal measurable impacts to the resources examined within these regions and therefore, Negligible impacts are anticipated.

4.3.2.4.5 Alternative 5

4.3.2.4.5.1 Appalachian Basin Region

Analysis suggests that this Alternative would cause a slight decrease in total coal production for this region, coupled with a minor shift towards underground mining. Such changes would decrease the total area of affected land use, reduce infrastructure demands, and lessen adverse impacts on visual resources and noise. In addition, the area disturbed per million tons of coal mined would decrease. Improved reforestation would create beneficial impacts on land use and visual resources. Taken together, this Alternative is anticipated to have a long term and medium scope impact and, thus, is classified as an overall Moderate Beneficial effect on land use, utilities, infrastructure, visual resources, and noise.

4.3.2.4.5.2 All Other Regions

The analysis for this Alternative shows minimal measurable impacts to the resources examined within these regions and therefore, Negligible impacts are anticipated.

4.3.2.4.6 Alternative 6

4.3.2.4.6.1 All Regions

The analysis for this Alternative shows minimal measurable impacts to the resources examined and therefore, Negligible impacts are anticipated.

4.3.2.4.7 Alternative 7

4.3.2.4.7.1 Appalachian Basin Region

Analysis suggests that this Alternative would cause a slight decrease in total coal production for this region, coupled with a minor shift towards underground mining. Such changes would decrease the total area of affected land use, reduce infrastructure demands, and lessen adverse impacts on visual resources and noise. In addition, the area disturbed per million tons of coal mined would decrease. Improved reforestation would create beneficial impacts on land use and visual resources. Taken together, this Alternative is anticipated to have a long term and medium scope impact and, thus, is classified as an overall Moderate Beneficial effect on land use, utilities, infrastructure, visual resources, and noise.

4.3.2.4.7.2 Colorado Plateau Region and Gulf Coast Region

The analysis for this Alternative shows minimal measurable impacts to the resources examined within these regions and therefore, Negligible impacts are anticipated.

4.3.2.4.7.3 Illinois Basin Region

Analysis indicates that this Alternative would slightly decrease total coal production in this region, thereby slightly decreasing the total area of affected land use, reducing infrastructure demands, and lessening adverse impacts on visual resources and noise. Therefore, this Alternative would likely have long term and small scope impact, and, thus, is classified as an overall Minor Beneficial effect on land use, utilities, infrastructure, visual resources, and noise.

4.3.2.4.7.4 Northern Rocky Mountains and Great Plains Region, Northwest Region, Western Interior Region

The analysis for this Alternative shows minimal measurable impacts to the resources examined within these regions and therefore, Negligible impacts are anticipated.

4.3.2.4.8 Alternative 8 (Preferred)

4.3.2.4.8.1 Appalachian Basin Region

Analysis suggests that this Alternative would cause a slight decrease in total coal production for this region. Such changes would decrease the total area of affected land use, reduce infrastructure demands, and lessen adverse impacts on visual resources and noise. In addition, the area disturbed per million tons of coal mined would decrease. Improved reforestation would create beneficial impacts on land use and visual resources. Taken together, this Alternative is anticipated to have a long term and medium scope impact and, thus, is classified as an overall Moderate Beneficial effect on land use, utilities, infrastructure, visual resources, and noise.

4.3.2.4.8.2 Colorado Plateau Region and Gulf Coast Region

The analysis for this Alternative shows minimal measurable impacts to the resources examined within these regions and therefore, Negligible impacts are anticipated.

4.3.2.4.8.3 Illinois Basin Region

Analysis indicates that this Alternative would decrease total coal production in this region, thereby decreasing the total area of affected land use, reducing infrastructure demands, and lessening adverse impacts on visual resources and noise. Therefore, this Alternative would likely have long term and small scope impacts, and, thus, is classified as an overall Minor Beneficial effect on land use, utilities, infrastructure, visual resources, and noise.

4.3.2.4.8.4 Northern Rocky Mountains and Great Plains Region, Northwest Region, Western Interior Region

The analysis for this Alternative shows minimal measurable impacts to the resources examined within these regions and therefore, Negligible impacts are anticipated.

4.3.2.4.9 Alternative 9

4.3.2.4.9.1 All Regions

Alternative 9 would require the repromulgation of the currently vacated 2008 Stream Buffer Zone rule. This Alternative would require minimization of excess spoil generation, place limits on excess spoil fill capacity to match the anticipated amount of excess spoil to be generated, and prohibit mining activities in or within 100 feet of an intermittent or perennial stream unless the applicant demonstrates and the regulatory authority finds that avoidance is not reasonably possible. The model mines analysis indicates that the impacts of Alternative 9 would not differ significantly from those of the No Action Alternative because the Clean Water Act requirements and policies discussed in the Regulatory Impact Analysis for this rulemaking and the state AOC and excess spoil policies identified in Section 4.2.3.1 of this FEIS have effectively achieved implementation of this Alternative in Central Appalachia, which is the region in which the 2008 Stream Buffer Zonerule would have had its greatest impact if it had remained in effect. Therefore, if repromulgated, Alternative 9 would now have Negligible on land use, utilities, infrastructure, visual resources, and noise evaluated in this FEIS.

Table 4.3-31. Summary of Impacts of the Action Alternatives on Land Use, Utilities, Infrastructure, Visual Resources, and Noise Compared to the No Action Alternative

Alternative	Metric	Appalachian Basin	Colorado Plateau	Gulf Coast	Illinois Basin	Northern Rocky Mountains and Great Plains	Northwest	Western Interior	National
Alternative 2	**Classification**	Moderate Beneficial	Negligible	Negligible	Minor Beneficial	Minor Beneficial	Negligible	Negligible	Minor Beneficial
	Rationale	LT, MS	MMI	MMI	LT, SS	LT, SS	MMI	MMI	
Alternative 3	**Classification**	Moderate Beneficial	Negligible	Negligible	Minor Beneficial	Negligible	Negligible	Negligible	Negligible
	Rationale	LT, MS	MMI	MMI	LT, SS	MMI	MMI	MMI	
Alternative 4	**Classification**	Moderate Beneficial	Negligible	Negligible	Minor Beneficial	Negligible	Negligible	Negligible	Negligible
	Rationale	LT, MS	MMI	MMI	LT, SS	MMI	MMI	MMI	
Alternative 5	**Classification**	Moderate Beneficial	Negligible	Negligible	Negligible	Negligible	Negligible	Negligible	Negligible
	Rationale	LT, MS	MMI	MMI	MMI	MMI	MMI	MMI	
Alternative 6	**Classification**	Negligible	Negligible	Negligible	Negligible	Negligible	Negligible	Negligible	Negligible
	Rationale	MMI	MMI	MMI	MMI	MMI	MMI	MMI	
Alternative 7	**Classification**	Moderate Beneficial	Negligible	Negligible	Minor Beneficial	Negligible	Negligible	Negligible	Negligible
	Rationale	LT, MS	MMI	MMI	LT, SS	MMI	MMI	MMI	
Alternative 8 (Preferred)	**Classification**	Moderate Beneficial	Negligible	Negligible	Minor Beneficial	Negligible	Negligible	Negligible	Negligible
	Rationale	LT, MS	MMI	MMI	LT, SS	MMI	MMI	MMI	
Alternative 9	Classification	Negligible	Negligible	Negligible	Negligible	Negligible	Negligible	Negligible	Negligible
	Rationale	MMI	MMI	MMI	MMI	MMI	MMI	MMI	

Notes:
LT = Long-term impact; MS = Medium scope impact; SS = Small scope impact; MMI = Minimal measurable impact.
Please see Section 4.0 for a definition of Negligible, Minor, and Moderate impact terms used above.
For a discussion of the impacts of the No Action Alternative (Alternative 1), see Section 4.2.3.1.

4.3.3 Recreation

Recreational resources are those features that support activities pursued for enjoyment, leisure, pleasure, or relaxation. For example, rivers and streams may support boating and fishing, and forested landscapes may provide opportunities for hunting or hiking. Changes to these resources alter the recreational activities they sustain. While such activities vary extensively, recreation is characterized, in the context of this analysis, in terms of outdoor activities occurring within a natural landscape. Specifically, this chapter explores the impacts of the Action Alternatives on land- and water-based recreational opportunities within each of the seven coal regions compared to the No Action Alternative. These recreational activities, including hunting, wildlife viewing, trail use, boating, and fishing, may occur on both public and private lands within the study area.

The discussion of recreational impacts is organized as follows:

- The first subsection reviews the existing regulatory environment and its implications for recreation. It identifies specific elements of the Action Alternatives that could affect recreational opportunities, contrasting these elements to requirements under the No Action Alternative.
- Next, the discussion considers existing recreational resources in the region and quantifies the extent to which the Action Alternatives could enhance or degrade those resources.
- The final subsection summarizes the impacts of the Action Alternatives, characterizing these impacts by region.

4.3.3.1 Effects of the Current Regulatory Environment (the No Action Alternative)

4.3.3.1.1 Current Restrictions on Coal Mining Location

Section 522(e) of SMCRA (30 U.S.C. § 1272(e)) requires that certain recreational resources not be disturbed by mining. Specifically, surface coal mining operations must not be permitted “within the boundaries of units of the National Park System, the National Wildlife Refuge Systems, the National System of Trails, the National Wilderness Preservation System, the Wild and Scenic Rivers System, including study rivers designated under section 5(a) of the Wild and Scenic Rivers Act and National Recreation Areas designated by Act of Congress” (30 U.S.C. § 1272(e)(1)). In addition, mining is not allowed on any federal lands within the boundaries of any national forest; in areas that would adversely affect any publicly owned park or place on the National Register of Historic Places; or within 300 feet of a public park (30 U.S.C. § 1272(e)(2), (3), and (5); *see also* 30 CFR Part 761. The exception would be where the operation qualifies as existing under 30 CFR 761.12 or an applicant has valid existing rights under 30 CFR 761.16. However, since the enactment of SMCRA over three decades ago, the frequency of valid existing rights claims is declining.

30 CFR 761.11(c) specifies that if a proposed surface coal mining operation would have an adverse impact on a publicly owned park or place in the National Register of Historic Places, the proposed operation cannot be authorized unless both the SMCRA regulatory authority and the agency with jurisdiction over the park or place jointly approve the operation. In essence, if adverse impacts are identified, under 30 CFR 780.31(a) or 784.17(a) the applicant must prepare a plan to prevent adverse impacts, or (if approved by both agencies) to minimize adverse impacts.

Section 522 of SMCRA also establishes a process for designating areas as unsuitable for surface coal mining operations. For example, areas may be designated unsuitable if the operations would "affect fragile or historic lands in which such operations could result in significant damage to important historic, cultural, scientific, and esthetic values and natural systems" (30 U.S.C. § 1272(a)(3)(B); *see also* 30 CRF Part 762). Such "fragile or historic lands" might include recreational resources. Under Section 522(b) of SMCRA, before mining is allowed to occur, all federal lands must be evaluated using the unsuitability criteria (30 U.S.C. § 1272(b)). Finally, SMCRA allows anyone with an interest that is or may be adversely affected to petition the appropriate SMCRA regulatory authority to have certain lands, including fragile or historic lands, designated unsuitable for mining under the unsuitability criteria (30 U.S.C. § 1272(c) *see also* 30 CFR Parts 764 and 769). Numerous petitions have been filed under this process. Some have been denied, some approved and some partially approved. Most of the petitions have been filed in primacy states, and OSMRE does not maintain records of the number of petitions nationwide, the primary concerns that form the basis of these petitions, or the number of acres ultimately designated as a result.

4.3.3.1.2 Potentially Affected Recreational Resources

Understanding recreational resources and the existing level of recreational activity in each of the coal regions provides context for assessing the Action Alternatives. Public lands, including federal, state, and locally managed lands, are often popular destinations for recreators due to the relatively natural and undeveloped quality of those lands. In addition, private lands are also used for recreation. Table 4.3-30 characterizes the areas of federal, state, municipal, protected lands within the study area by state, as well as lands owned by non-governmental organizations and private landowners which have been reported as being set aside for conservation or protection. These figures were estimated using USGS' Protected Areas Database of the U.S. (PAD-US), which includes public land ownership and conservation lands, including voluntarily provided privately protected areas, for the continental United States, Alaska, Hawaii and Puerto Rico. (USGS, 2016).

Hunting is not allowed on all areas classified as protected. For example, although hunting is permitted on some National Park Service (NPS) lands, hunting is not generally allowed on NPS lands. However, National Forests, U.S. Bureau of Land Management (BLM) lands, and National Recreation Areas often allow hunting. Approximately 60 percent of U.S. Fish and Wildlife Service (U.S. FWS) land allows hunting.

The 2011 edition of the U.S. FWS's *National Survey of Fishing, Hunting, and Wildlife-Associated Recreation* (USFWS 2011 survey) provides comprehensive data at the state level characterizing participation in hunting, wildlife viewing, and fishing. The survey reports the total number of hunter-days, wildlife viewing-days, and fishing-days for each state.[49] According to the USFWS survey, 13.7 million people hunted in the U.S. in 2011. Of these, 4.9 million hunters, or 36 percent of all hunters in the U.S., hunted on public lands and 1.7 million, or 13 percent of all hunters, exclusively hunted on public lands. Almost a third of the U.S. population over the age of 16, or nearly 72 million residents, took part

[49] Activity levels are measured as the activity of one participant over the course of one day. For example, two individuals hunting for a total of three days together would generate six hunter-days.

in wildlife viewing activities and 33.1 million residents over the age of 16 participated in fishing activities in 2011 (USFWS 2011).

Table 4.3-33 shows the USFWS 2011 survey estimates of total annual hunting, wildlife viewing, and fishing days for each state that intersects the study area.

Table 4.3-32. Protected Land Ownership Within the Study Area, by State

Geography	Percent Study Area Protected	Federal (thousands of acres)1	State/ Local Government (thousands of acres)2	Private (thousands of acres)3	Total Protected in Study Area (thousands of acres)

Source: Acres of protected lands calculated using GIS analyses on databases provided by USGS (USGS National Gap Analysis Program, May 5, 2016. Available at **http://gapanalysis.usgs.gov/padus/data/**)
Note: Recreational resources listed above are restricted to those that fall within the study area in each region. As detailed in Section 4.0, the study area represents areas where future coal mining is expected to occur based on past mining activity. Values have been rounded to two significant figures.
Includes lands that are jointly managed.
Includes lands that are managed by regional agencies.
Includes lands that are owned/managed by non-governmental organizations, as well as a small amount of protected lands with "unknown" ownership.

For this analysis, the study area encompasses all geographic areas likely to be affected by the Action Alternatives. The total value of recreational activity in states which intersect each coal region is estimated based on average, per-day value parameters in the economics literature and the 2011 FWS survey estimates of the frequency of hunting, fishing, and wildlife viewing reported above. Adjusted to 2014 dollars,[50] these consumer surplus[51] values per person, per day of activity are estimated at $57.16, $51.61, and $57.46 for hunting, wildlife viewing, and fishing, respectively (Loomis, 2005).[52] By multiplying these value estimates by the total activity level for each recreational opportunity in all states, the total annual economic value of the recreational activities is determined. The results generated for hunting, wildlife viewing, and fishing in each of the seven coal regions are provided in Tables 4.3-34 and 4.3-34. Specifically, these tables characterize the relative importance of the states within the coal mining

[50] Values were adjusted using the Bureau of Labor Statistics' CPI Inflation Calculator. www.data.bls.gov/cgi-bin/cpicalc.pl.

[51] Consumer surplus is the difference between the maximum amount that an individual would be willing to pay for a day of recreation and the price that the individual actually pays (in the form of recreational expenditures). Natural resource economists use consumer surplus as a measure of the net economic welfare that an individual enjoys as a result of a recreational experience.

[52] In his report, Loomis summarizes thirty years of the literature on net economic value of outdoor recreation on public lands at the national level. It is likely that these value estimates for recreational activities vary by region; however, the literature does not currently provide more geographically specific per-day values.

regions in providing recreational opportunity using two indicators: (1) the level of recreational activity on the public lands within the states; and (2) the total value of these recreational opportunities.

Table 4.3-33. Annual Recreational Activity Levels, for States with Active Coal Mining that Intersect the Study Area (2011)

Geography	Percent of State in the Study Area	Annual Hunting Days (millions)	Annual Wildlife Viewing Days (millions)	Annual Freshwater Fishing Days (millions)	Total Activity Days (millions)

Source: Activity values taken from John Loomis's 2005 publication Updated Outdoor Recreation Use Values on National Forests and Other Public Lands.
Note: Value of annual hunting, fishing, and wildlife viewing activity for each coal region is the sum of the state totals within the region. All values have been rounded to two significant figures. For states that intersect more than one coal region, reported values are split evenly.

These available data support the following comparison or recreational resource availability by coal region:

- **Appalachian Basin Region**: The study area comprises approximately 18 percent of the land area in the Appalachian Basin (ranging from four to 49 percent depending on the state). Protected lands in this region are predominantly split between state and federal land managers. Notably, 49 percent of the State of West Virginia falls within the study area. Approximately ten percent of the overall study area in this region is protected (3.4 million acres of protected lands). Fishing is a relatively popular activity in the Appalachian Basin region in comparison to the other coal regions, partly due to the extent of rivers and streams. In fact, the FWS 2011 survey reports that the states in the Appalachian Basin coal region had the highest annual hunting, wildlife viewing, freshwater fishing days, and associated recreational values of all coal regions in 2011, with a combined total of 200 million recreation days valued at $11 billion.

- **Colorado Plateau Region**: The study area comprises approximately three percent of the land area in the Colorado Plateau (ranging from less than one to five percent depending on the state). While the study area is small relative to the overall land area of the region, this region has the largest overall protected acreage of all coal regions (6.6 million acres). Of the study area lands, approximately 81 percent is protected, primarily in New Mexico, Colorado, and Utah. The FWS 2011 survey reports that the states in the Colorado Plateau Region had a total of 62 million total hunting, wildlife viewing, and fishing days in 2011, ranging from 11 million days in New Mexico to 19 million days in Arizona.

- **Gulf Coast Region**: The study area comprises four percent of the land area in the Gulf Coast region (ranging from two to four percent depending on the state). Approximately two percent of the study area (130 thousand acres) is protected. While the study area and protected area in this region is small relative to the overall land area of the region, of all states in coal regions Texas had the highest annual hunting, wildlife viewing, and freshwater fishing days in 2011, with a combined total of 63 million days. All states in the Gulf Coast Region had a total of 110 hunting, wildlife viewing, and fishing days in 2011.

- **Illinois Basin Region**: The study area comprises approximately 24 percent of the Illinois Basin. Notably, 41 percent of the State of Illinois is included in the study area. Approximately four percent of the study area in the Illinois Basin is protected (790 thousand acres of protected lands). The total hunting, fishing, and wildlife viewing days in the states in the Illinois Basin was 88 million in 2011. Fishing was a particularly popular activity in the study area's states with the second highest annual fishing days among all regions' states in 2011.

- **Northern Rocky Mountains and Great Plains Region**: The study area comprises approximately four percent of the land area in the Northern Rocky Mountains and Great Plains Region (ranging from two to six percent by state). Approximately 25 percent of the study area is protected, most of which is federally owned. Notably, approximately 31 percent of the study area in Montana is currently protected. The total hunting, wildlife viewing, and fishing days in the region's states was 34 million in 2011, ranging from 2.6 million days in North Dakota to 18 million days in Colorado. Among all states in the coal study regions, North Dakota had the lowest annual wildlife viewing and freshwater fishing days.

- **Northwest Region**: The study area comprises less than one percent of the land area in the Northwest region which is represented only by a small area within the State of Alaska (230 thousand acres are in the study area. Of the small area in the study area, approximately 98 percent is protected (220,000 acres of protected lands). There were a total of 11 million hunting, wildlife viewing, and fishing days in Alaska in 2011. Note that, while Alaska has abundant pristine, natural land that is optimal for recreational activities, very little coal mining currently occurs in this State or in the Northwest Region, and therefore the recreational resources within the study area that could be affected by the Action Alternatives are limited.

- **Western Interior Region**: The study area comprises approximately two percent of the land area in the Western Interior Region (ranging from one to five percent by state). Approximately ten percent of the study area is protected (440 thousand acres of protected lands). Notably, 24 percent of Arkansas is protected. The hunting, wildlife viewing, and fishing days in the region's states was approximately 88 million in 2011, ranging from 10 million days in Kansas to 33 million days in Missouri. The total value of the recreational activity in the region's states was five billion dollars in 2011.

4.3.3.1.3 Caveats and Uncertainties

Several constraints limit the analysis of potentially affected recreational resources and activities across regions.

- The U.S. FWS recreation survey only tracks hunting, wildlife viewing, and fishing. Other recreational activities also dependent on forest or water, such as hiking, ATV use, boating, and swimming, may also benefit from the Action Alternatives. No systematic, national data exist to characterize activity levels for these recreational pursuits.

- Currently, SMCRA prohibits mining on certain categories of federal lands, including lands within the National Park System. However, these protected areas may experience indirect affects by mining activities on adjacent lands, through habitat disruption and visual and noise impairment.

- Additional private lands not captured in the PAD-US data which support mining currently or in the future may also provide recreational opportunities. While not accounted for in the analysis of recreational land, this recreation on private land could be affected by the Action Alternatives.

- Public commenters have pointed out that many state wildlife agencies in coal-producing states collect very good data on hunter harvest of deer, elk, bears, and turkeys on public and private lands. Commenters also point out that state wildlife agencies have some formal hunter access agreements with large corporate landowners in coal-producing counties. Unfortunately, the data on recreational visitation to private lands are inconsistent on a national scale, and do not provide sufficient data to understand the extent and quality of private land habitats and how these characteristics could be affected by the alternatives considered. The metrics captured in hunter harvest data (e.g. hunter success rates, days of effort per harvested animal, total days of effort, number of licenses sold) present a valuable snapshot of historic and current hunter activity. However this data provides no additional insight on expectations for future management of private lands or expectations of future hunter harvests with or without implementation of any particular alternative. Management of public lands is more predictable and subject to overarching goals that are established under public review.

- The quantified results do not specifically capture the occasional practice that occurs under the No Action Alternative, in which reclaimed land is designated specifically for recreational uses. This practice may be accompanied by a conveyance of private reclaimed land to the public. Designating reclaimed land for recreational purposes may increase recreational use after mining relative to premining conditions. No systematic data exist for assessing the frequency of this practice. If mining decreases, however, some land that under the No Action Alternative would have been mined, reclaimed, and converted to a public recreational resource may remain unmined and in private control, unavailable to recreators.

- Finally, the use of national or coal region averages for consumer surplus values or recreational activity levels, respectively, can mask more nuanced variation. For example, the per-day use value of hunting may be greater in the Appalachian Basin than in the Gulf Coast; however, this difference would not be captured in the application of the national average for hunting value to both coal regions.

4.3.3.2 Action Alternatives and Potential Effects on Recreational Resources

Various elements of each Alternative may affect either the quantity or quality of recreational activities within the coal mining regions. Quantity refers to the number of recreational outings taken, while quality refers to the utility (defined by economists as a sense of well-being) that individuals derive from a recreational experience. For example, an increase in the abundance of wildlife may lead to more wildlife viewing excursions (quantity) and may also lead to a greater diversity of species observed during each excursion (quality).

Table 4.3-35 summarizes the recreational activities potentially affected by the various elements of the Action Alternatives. The following discussion describes how each of the elements may affect recreation within the coal regions, and why certain elements are not expected to affect recreation. Full descriptions of the elements and how they vary across Alternatives can be found in Chapter 2.

Table 4.3-35. Action Alternatives Elements and Potential Effects on Recreational Activities

Action Alternatives Element	Hiking	ATV Use	Hunting	Wildlife Viewing	Fishing	Swimming	Boating
Baseline Data Collection and Analysis					■	■	■
Monitoring During Mining and Reclamation					■	■	■
Definition of Material Damage to the Hydrologic Balance					■	■	■
Evaluation Thresholds					■	■	■
Mining Through Streams					■	■	■
Activities In or Near Streams Including Excess Spoil and Coal Refuse	■			■	■	■	■
AOC Variances	■	■		■	■	■	■

Revegetation, Topsoil Management, and Reforestation	■	■	■	■			
Wildlife Protection and Enhancement			■	■	■		

Table 4.3-35 links the elements with popular outdoor activities, both land- and water-based. Land-based recreational activities include hunting, wildlife viewing, hiking, and all-terrain vehicle (ATV) use.[53] These activities may be affected by the Action Alternatives to the extent that the Alternatives: (1) reduce or increase the number of trails or the land area available to support them; (2) result in degraded or improved wildlife habitat and populations; or (3) generate more or less natural, aesthetically-pleasing landscapes. Common water-based activities include boating, swimming, and fishing. These activities may be altered by elements of the Alternatives that affect the quality, quantity, or accessibility of water resources.[54] In addition, to the extent an Alternative reduces coal mining activity in a region recreational areas may be preserved resulting in an indirect benefit to some areas.

[53] Use of all-terrain vehicles is an outdoor activity which has become increasingly popular, particularly in rural areas (Cribari, 2002).

[54] The link between water quality and value of water-based recreational activity has been established in the literature (Koteen, et al., 2002; Hayes, et al., 1992).

4.3.3.2.1 Protection of the Hydrologic Balance

4.3.3.2.1.1 Baseline Data Collection and Analysis

The rule elements associated with baseline data collection and analysis serve to specify water sampling and analysis procedures.

- Under the No Action Alternative (Alternative 1) some requirements for baseline data collection and analysis exist, as described in Chapter 2. Data characterizing premining conditions allow mine operators and regulators to identify the incremental effects of the mining activity on monitored water quality parameters.
- The Action Alternatives (excluding Alternative 9) standardize the sampling protocol and increase the assessment and monitoring activities for baseline data collection and analysis, as described in Chapter 2. These changes are not expected to directly affect recreational activities but may lead to indirect effects on recreational resources to the extent that they promote improved water quality in the region.
- The requirements of Alternative 9 with respect to this element are the same as the No Action Alternative and, as such, their effects on recreational resources are the same as the No Action Alternative.

4.3.3.2.1.2 Monitoring During Mining and Reclamation

The Alternatives require the collection and review of stream hydrologic parameters, both during mining and following mining.

- Under the No Action Alternative, the metrics required for monitoring are limited, and the frequencies with which data should be collected are undefined.
- The Action Alternatives establish timeframes for data monitoring and review and include additional metrics to be collected. Such changes are not expected to have a direct effect on recreational opportunities, but could lead to indirect improvements in recreational resources to the extent that they promote improved water quality in the region.
- The requirements of Alternative 9 with respect to this element are the same as the No Action Alternative and, as such, their effects on recreational resources are the same as the No Action Alternative.

4.3.3.2.1.3 Definition of Material Damage to the Hydrologic Balance

Both SMCRA and the implementing regulations use the phrase “material damage to the hydrologic balance outside the permit area,” but they do not define this term.

- The No Action Alternative represents the status quo, which regulates material damage to the hydrologic balance but does not define the term. Without a formal definition of the term or enforcement of the protection of it, negative impacts to either quantity or quality of aquatic recreational resources may occur. Stream loss may directly cause a reduction in boating, swimming, and fishing due to the loss of the recreational resource for streams that supported such uses. Diminished water quality or biological condition (as described in previous sections of this chapter) may adversely affect aquatic habitats and the fish which live in them leading to a reduction in fishing activity or a diminished fishing experience (e.g., due to reduced catch rates). Similarly, such contamination of surface water may lead to a waterway failing to meet the water quality requirements for the designated use of swimming, resulting in fewer swimming trips.

- Alternatives 2, 3, 4, and 8 (Preferred) require a formal definition of material damage to the hydrologic balance outside the permit area. Under this more precise definition, adverse impacts to the quantity or quality of off-site groundwater and surface water would be more quantifiable and demonstrable. As such, water quality impacts could be more readily avoided and water quality standards could be more easily enforced. This increases the likelihood that surface waters would maintain their designated uses under the Clean Water Act, allowing for increased fishing and swimming opportunities as compared to the No Action Alternative. The definition may also help preserve the existence of water bodies, increasing the availability of recreation that is not directly dependent upon water quality, e.g., boating.

- Alternatives 5, 6, and 9 are identical to the No Action Alternative and do not require a formal definition of material damage to the hydrologic balance. As such, the effects on recreational resources are the same as the No Action Alternative.

- Alternative 7 requires a formal definition of material damage to the hydrologic balance on a case-by-case basis whenever enhanced permitting conditions are required.[55] As such, adverse impacts to water resources may be reduced but only at some mining sites under certain circumstances.

4.3.3.2.1.4 Evaluation Threshold

Evaluation thresholds are standards set lower than those for material damage to the hydrologic balance and are designed to act as a type of early detection system to prevent material damage to the hydrologic balance from occurring.

- Under the No Action Alternative, permit specific monitoring data are used to estimate hydrologic conditions and to determine the need for evaluation. No requirement for specific evaluation thresholds exists.

- Under Alternatives 2, 3, 4, and 8 (Preferred), the evaluation thresholds may improve the likelihood that material damage to the hydrologic balance is avoided. As discussed above for material damage to the hydrologic balance, the avoidance of impacts to off-site ground and surface water would help maintain and preserve water based recreational opportunities such as fishing, swimming, and boating.

- Alternatives 5, 6, and 9 are the same as the No Action Alternative and do not establish evaluation thresholds. Therefore, the effects on recreational resources are the same as the No Action Alternative.

---

[55] See Chapter 2 for an explanation of enhanced permit conditions.

- Alternative 7 is similar to Alternatives 2 through 4 but the evaluation thresholds and the adaptive management plan drafted to avoid material damage to the hydrologic balance apply only to the designated enhanced permit areas. In some cases, Alternative 7 may result in effects to recreational resources as compared to the No Action Alternative. As described for Alternatives 2 through 4 above, however, impacts stemming from evaluation thresholds are considered to be indirect because the purpose of the thresholds is to avoid material damage to the hydrologic balance.

4.3.3.2.2 Activities In or Near Streams

4.3.3.2.2.1 Stream Definitions

Alternatives 2, 4, 7 and 8 (Preferred) would change the regulatory definition of streams. Alternatives 3, 5, 6, and 9 would retain the current definition of the No Action Alternative. Current regulations classify all watersheds one square mile or larger in size as intermittent streams; some of the Action Alternatives would delete this provision. To the extent that this change would result in some streams (mostly in the arid and semiarid regions of the West) now protected as intermittent streams being reclassified as ephemeral streams, which lack the protections afforded to perennial and intermittent streams, there could be a direct effect on the water resources and therefore an indirect effect on recreational use of those streams.

4.3.3.2.2.2 Mining through Streams

Under the No Action Alternative, water-dependent recreational activities may be negatively impacted in the event that mining occurs through a stream. Although the quantity of water may remain unchanged in the long-term when mining occurs through a stream,[56] short-term diversions of the stream may change flow volume, limiting the opportunity for and/or utility of downstream boating and swimming. The aquatic habitat of downstream waters may also be negatively altered due to the temporary disruption and diversion of the waterway, leading to suppressed numbers of fish.

Alternatives 2 through 8 (Preferred) add restrictions to the approval process for mining through streams. For each of these Alternatives, specific performance standards would be required to guide stream restoration.[57] The return of natural hydrologic form and biological condition and function of the stream would be required by such restoration.

- Alternative 2 explicitly prohibits all mining activities in or within 100 feet of a perennial stream and require that all ephemeral streams be restored in form. Alternative 7 has the same requirements when enhanced permit requirements are imposed. Under these Alternatives, not only would the restored streams be expected to be of better quality than those under the No Action Alternative, but also fewer streams would be expected to be affected overall. Less disruption of the aquatic resource on-site may yield improved water quality, greater stream flow,

[56] Section 404 of the Clean Water Act calls for no net loss of aquatic resources.

[57] For Alternative 5, the application of all element components, including these performance standards, is limited to mining activities that result in placement of excess spoil outside the mined area or coal refuse disposal in perennial or intermittent streams. For Alternative 6, the application of components is limited to stream buffer zones.

and reduced impacts on aquatic habitat downstream, leading to more boating, swimming, and fishing trips.

- Alternatives 3, 4, 5, 6, and 8 (Preferred) allow mining through streams as long as a reclamation plan achieving complete restoration of the hydrologic form and ecological function of perennial and intermittent streams is approved in advance of mining. Further, some ephemeral streams will require restoration of stream form. These regulations would likely improve water quality and positively impact downstream recreational activities as described above for Alternatives 2 and 7, but not to the same extent as those two Alternatives.

- The requirements for this element under Alternative 9 are not expected to be functionally different from those under the No Action Alternative. Therefore, the effects on recreational resources are the same as the No Action Alternative.

As described above, under the No Action Alternative, restoration occurs for perennial and intermittent streams. The Action Alternatives would require restoration of ephemeral streams as well. Because ephemeral streams are defined by their lack of continuous flow, their value for recreational resources may be less than that of more permanent waterways. Therefore, restoring an ephemeral stream may have less impact recreational resources than restoration of an intermittent or perennial stream.

4.3.3.2.2.3 Activities In or Near Streams, Including Excess Spoil and Coal Refuse

Mining activities in and within 100 feet of streams and the treatment of excess spoil and coal refuse possess the potential to adversely affect the quantity and quality of downstream water. These adverse impacts may result from the diversion of streams as part of the mining process (leading to a change in stream flow as described above) or from the discharge of pollutants into the downstream waters from the placement of spoil and/or refuse near streams.

- Under the No Action Alternative, mining activities within 100 feet of a stream are prohibited unless authorized by the appropriate regulatory authorities. OSMRE and most state regulatory authorities allow the construction of spoil fills in intermittent and perennial streams within the permit area. Additionally, flat decks on top of fills are allowed and there is no requirement for final configuration to incorporate appropriate topography.

- Alternatives 2 through 8 (Preferred) increase the stringency of the requirements that guide mining activities near streams and the placement of excess spoil and refuse. Some of these Alternatives also add provisions for allowable fill construction techniques, increased monitoring during fill construction, and the incorporation of appropriate topography when constructing the fill.[58] Alternatives 2, 3, and 7 specifically reduce the amount of streams filled from underground mining by prohibiting filling of perennial streams. Such standards serve to decrease the likelihood that a stream would be diverted during coal mining, changing its flow and the probability that higher concentrations of pollutants would adversely affect

[58] The consequences of AOC regulations on recreational resources are discussed in detail in the AOC Variances section below.

downstream fish populations. With more reliable flow volume and less pollutants, water-based recreational activities such as boating, swimming, and fishing may be enhanced.

- The requirements for this element under Alternative 9 are not expected to be functionally different from those under the No Action Alternative. Therefore, the effects on recreational resources are the same as the No Action Alternative

4.3.3.2.3 Approximate Original Contour (AOC)

4.3.3.2.3.1 AOC Variances

AOC variances allow exceptions to the requirement that the landscape be returned to its near original configuration; therefore, this element is particularly relevant for mountaintop removal and steep-slope mining. Currently, for both mountaintop removal and steep-slope mining, beneficial postmining land use (PMLU) must be proposed, with a demonstration of equal or better use. Neither type of mining operation, however, is required to reforest the permitted area during reclamation.[59] For mountaintop removal mining, the natural watercourses below the lowest coal seam mined must remain undamaged. For steep-slope mining, deviations from AOC are limited to circumstances when lands will be improved by issuing the variance. The components encompassed by this element most directly affect land quality available for trails and habitat.

- Under the No Action Alternative, the most discernible consequence of the allowable AOC variances is the alteration of visual resources associated with PMLUs. The utility, or well-being that recreating individuals, be they hikers or wildlife-viewers, derive from the land is diminished after postmining activity. Mountain landscapes are preferred as an environmental land type for recreational opportunities because of their appeal to the aesthetic senses (Raitz and Dakhil, 1988).

- Alternative 2 eliminates AOC variances entirely. This Alternative maintains original mountain and steep-slope landforms.[60] As such, land-based recreational activities, such as hiking, wildlife viewing, and possibly ATV use would be expected to have greater utility for participants. In addition, Alternative 2 would result in fewer impacts to streams which should benefit recreational users. Aesthetic benefits may also result.

- Alternatives 3, 4, 5, and 8 (Preferred) increase the requirements for an AOC variance approval. This means that fewer AOC variances would be granted, reducing adverse impacts to natural watercourses (mountaintop removal), surface water flow (steep-slope), and aquatic ecology (steep-slope), which would result in greater opportunities for boating, swimming, and fishing downstream. This should also result in fewer permanent effects on land use and visual resources.

- Alternatives 6, 7, and 9 do not differ from the No Action Alternative and thus would have the same effects as the No Action Alternative.

---

[59] The anticipated effects of reforestation on recreational resources are covered in the Revegetation, Topsoil Management, and Reforestation section below.

[60] Landforms are the natural physical features that comprise the terrain of the land, described in terms of elevation, slope, orientation, exposed rock, soil type, water bodies, wetlands, surface drainage pattern, drainageway characteristics, and other physical attributes of the land surface.

In some cases, limitation of AOC variances may curtail the potential for recreational activities that are not nature-based. For instance, leveling the grade of the land may allow for recreational opportunities that would not have otherwise been available in the area, particularly in areas where sloping terrain characterizes the un-mined land area. To the extent that AOC variances are used to prepare land for golf courses or soccer fields, for example, some of the Action Alternatives may reduce recreational opportunities (Minerals Education Coalition, 2014).

4.3.3.2.3.2 Surface Configuration

Surface configuration guides topography requirements both during mining activity and for postmining reclamation. As with the AOC element described above, the effects of reforming the land may most prominently include the aesthetic consequence on appreciative outdoor activities, including hiking and wildlife viewing.

- Under the No Action Alternative, few provisions are in place to guide landscape formation following mining: for example, digital terrain analyses and the use of land forming principles are not required and limits on final elevations are absent.[61]

- Alternatives 2 and 4 add elevation limitations (the backfilled area must not vary from the premining elevation by ±20 percent) and may result in greater beneficial impacts than from the scenarios described for the No Action Alternative. These regulations may more strongly influence the final landforms, leading to better matching of the premining landscape, particularly for sites with topographic variability. This may, in turn, improve hiking and wildlife viewing experiences for recreating individuals.

- Alternatives 2, 3, and 4 would provide the most benefit to recreation from restoration of topography, as described in section 4.2.3, because they are most likely to ensure that the final surface configuration and landscape features more closely match the premining configuration and landscape features. The greatest benefit would occur in regions with highly variable premining topography, such as mountainous terrain. Alternatives 5 and 7 would produce less benefits to topography and consequently aesthetic benefits than Alternatives 2, 3, and 4, but more than the No Action Alternative.

- Alternatives 6, 8 (Preferred), and 9 are identical to the No Action Alternative and would have the same effects.

It should be noted that, for this rule element, the Alternatives 2, 3, 4,5 and 7 would likely have the greatest impact in regions where the premining topography is highly irregular, such as in the Appalachian Basin. The effect of the Action Alternatives on topography is analyzed in Section 4.2.3 Topography, Geology, and Soils.

---

[61] Land-forming is a design and grading technique that attempts to replicate the appearance of the natural terrain, as well as the water transport and water retention functions of that terrain, by constructing slopes, drainageways, and other surface features that blend with the natural surroundings in an environmentally compatible fashion while meeting any relevant stability requirements.

4.3.3.2.4 Postmining Land Use and Enhancement

4.3.3.2.4.1 Revegetation, Topsoil Management, and Reforestation

Postmining land cover is directed by the revegetation, topsoil management, and reforestation regulations. Under the No Action Alternative, reforestation is not required, though the establishment of vegetative cover is. Species native to the area are emphasized for use in revegetation, although introduced (non-native) species are permitted. Provided the mining operator demonstrates compliance with the regulations, selected overburden materials may be used in place of the topsoil removed from the disturbed area. Finally, the use of organic materials available within the disturbed areas is not required.

The absence of a reforestation requirement in the No Action Alternative may be the most pronounced of these conditions in contributing to adverse impacts on recreational opportunities. The natural succession of land cover from bare land to a forest can take between 15 to 20 years (Groninger, et al., 2007); at mining sites, succession can be further delayed by soil conditions, especially compaction. The initial loss of forest habitat or alterations to forest habitat (as the land advances through various successional stages) may have an adverse impact on the wildlife inhabiting these areas.[62] A loss in wildlife may negatively impact the recreational activities reliant on fauna, including hunting and wildlife viewing. Furthermore, during the extended period required for mature forest cover to develop, the utility derived by appreciative outdoor activities such as hiking may be diminished. Indeed, mountain forest landscapes have been demonstrated to be highly ranked in terms of scenic preference (Hammitt, et al., 1994). Reestablishing vegetative cover may benefit terrestrial recreational activities, including wildlife-viewing, hunting, and hiking. Conversely, such activities may be adversely impacted if previously forested land is not reforested following mining activity.

- Under the No Action Alternative, vegetative cover must be established following mining activity in accordance with the approved permit and reclamation plan. This vegetation may include introduced species. Not all soil horizons (i.e., underlying layers) are required to be salvaged and redistributed, and overburden materials may be used as a substitute for topsoil. Additionally, previously cleared land that had returned to forest through natural succession prior to mining activity does not have to be reforested. Under conventional practices, many mined lands are restored to grassland but are not used for hay or pasture. Natural succession of these lands to native forest may take hundreds of years (Angel, et al., 2005). Under favorable growth conditions, forest canopy closure often occurs 15 to 20 years after mine closure (Groninger, et al., 2007).

- Alternatives 2, 4, and 8 (Preferred) specify that the revegetation of reclaimed lands must be completed using only native species; the use of overburden materials as a replacement for, or as a supplement to, topsoil requires greater justification. In addition, the best available organic materials must be incorporated into the revegetation process, and reforestation of previously forested areas is required. These changes serve primarily to return the postmining land area to a native forest ecosystem as quickly as possible. By enhancing the return of the native forest ecosystem expeditiously, the requirements for this rule element could enhance hiking, hunting,

---

[62] In exceptional cases, changes in vegetation may enhance recreational opportunities. For instance, a habitat change may facilitate the return of a species that is appealing for hunting and viewing.

and wildlife viewing. The more rapid return of mature trees and abundant wildlife may enhance the quality of recreational activities that depend on such resources.

- Alternatives 3 and 5 are very similar to Alternatives 2, 4, and 8 (Preferred), except that salvage and redistribution of organic materials would be in accordance with an approved plan. As such, these Action Alternatives would also be expected to affect recreational activities enhanced by the existence of the native forest ecosystem.

- Alternatives 6 and 9 are identical to the No Action Alternative and no additional impacts are expected.

- Alternative 7 resembles Alternative 2 for this rule element, but applies only where designated enhanced permitting areas are proposed for mining. Therefore, the recreational impacts described for Alternative 2 apply, but under more limited circumstances.

4.3.3.2.4.2 Wildlife Protection and Enhancement

The Action Alternatives contain provisions to enhance fauna inhabiting the mine site and adjacent areas, including downstream aquatic life. Currently, no explicit, quantifiable guidance exists for wildlife protection (with perhaps the exception of the prohibition of surface mining activity likely to jeopardize endangered or threatened species). Current regulations provide qualitative goals, including the enhancement of fish and wildlife resources where practicable and the avoidance of disturbances to wetlands and streamside vegetation. The ambiguity in these standards means that mining activities may affect the aquatic and terrestrial habitats of non-endangered or non-threatened wildlife. Compromised habitat or complete loss of habitat may reduce the species abundance that the habitat can support. Recreational opportunities dependent on wildlife, including hunting, fishing, and wildlife viewing, may be adversely impacted as a result, either from reduced number of trips taken to areas with low population densities of the desired animals, or from diminished utility of each trip due to lower catch rates, bag rates, and sightings.

- Under the No Action Alternative, disturbances to fish and wildlife resources should be avoided and habitats restored or replaced where practicable. Enhancement of these resources is also required where practicable. In practice, these disturbances have often not been adequately restored, replaced, or enhanced. These requirements offer only general guidance for treatment of streamside habitats and habitats of unusually high value for fish and wildlife; no specific regulations guide these actions.

- Under Alternative 2, enhancement would be required if Clean Water Act mitigation was required, and the mitigation would be incorporated as a condition of the SMCRA permit. This alternative would require enhancement of fish and wildlife resources as well as habitats of unusually high value. For all stream reaches within or adjacent to coal mining operations, a 100-foot streamside vegetative corridor would be established. By implementing direct criteria to be met during and after coal mining operations, the likelihood of disrupting habitats and the wildlife that populates them is decreased. As such, the recreational resources supporting hunting, fishing, and wildlife viewing (i.e., fish and wildlife populations) may grow, leading to more trips taken and greater utility gained from each trip (e.g., as a result of increased wildlife sightings).

- Alternatives 3 and 4 would require enhancement measures to offset impacts, but unlike Alternative 2 these requirements would not necessarily have any direct bearing on the Clean Water Act mitigation and vice versa. These alternatives would require a 300-foot buffer zone around intermittent and perennial streams. These Alternatives also specifically detail the scenarios in which enhancement measures for fish and wildlife resources would be mandatory.[63] Similar to Alternative 2, Alternatives 3 and 4 decrease the probability that wildlife habitat, both aquatic and terrestrial, would be negatively impacted as a result of mining activity, though possibly not as strongly. As above, undisturbed habitats may lead to greater numbers of fish and wildlife which in turn would draw greater numbers of recreating individuals interested in hunting, fishing, or wildlife viewing. The quality of visits may also improve as the fulfillment of these activities is necessarily dependent on wildlife abundance.

- Alternative 8 (Preferred) would call for the same 100-foot streamside vegetative corridor as Alternative 2. It would also have wildlife enhancement requirements similar to those under Alternative 4, although it would not introduce the authority to prohibit mining of high-value habitats.

- Alternatives 5, 6 and 7 combine components of Alternatives 2 and 4, resulting in more protective measures for fish and wildlife. As detailed above, any action taken to promote or protect wildlife may indirectly improve the wildlife-related recreational activities by fostering improved species populations. Because the regulations under Alternatives 5, 6, and 7 apply only under defined circumstances, their overall impacts may be smaller than those expected under Alternatives 2, 3, 4, and 8 (Preferred).

- The requirements of Alternative 9 with respect to this element are the same as the No Action Alternative and, as such, their effects on recreational resources are the same as the No Action Alternative.

4.3.3.3 Assessment of Impacts to Recreational Activities

Without precise knowledge of future mine locations in relation to land-based recreational areas, modeling mining impacts on wildlife populations and related activities (e.g., hunting, viewing) is difficult. Similarly, the effect that landscape changes will have on the visual component of hiking cannot be characterized without understanding the precise spatial relationship between future mine locations and hiking opportunities. As such, a robust quantitative assessment of effects on land-based recreation is problematic.

Furthermore, sparse data exist to describe the effects of a coal mine, surface or underground, on wildlife populations. In the short term, reducing the availability of habitat through mining activities may result in a greater concentration of wildlife in adjacent hunting areas. The scale of the anthropogenic disruption associated with a coal mine, however, would also be expected to disrupt nearby wildlife, leading to a longer-term reduction in the abundance of animals for hunting. This is especially true for surface mines,

[63] These include the long-term loss of native forest, loss of native plant communities, or filling of a segment of a perennial or intermittent stream.

which generally pose a greater disruption to terrestrial habitat. Ultimately, without precise information describing the locations of mines in relation to existing recreational lands (especially private lands), and without data on how coal mining affects wildlife densities, a quantitative analysis would be highly speculative.

Beyond understanding the prevalence and value of recreational activities across the seven coal regions, it is also necessary to analyze if/how the Action Alternatives would affect recreational resources. The Action Alternatives can affect mining activities, and their associated consequences on recreational resources, in two ways. First, the Action Alternatives can improve mining and reclamation practices as described in Chapter 2, reducing effects on environmental resources such as streamside habitats and streams. Second, the Action Alternatives can change the level of coal production in a given region. Understanding this shift in mining activity allows for a more accurate assessment of the expected effects on recreation (i.e., increased mining may negatively impact recreational resources while decreased mining may have the opposite effect).

Forest loss and impaired stream miles are key examples of mining-related recreational losses. Therefore, a rough analysis of recreational impacts can proceed from an assessment of how the Action Alternatives influence these resources. Forest loss can reduce habitat for existing wildlife species, which in turn can impact the number of trips and quality of those trips taken to hunt or view the wildlife. Forest loss can also directly remove land available for hiking, ATV use, hunting, and wildlife viewing. For appreciative activities, such as hiking, forest loss can negatively impact aesthetic enjoyment. Impaired stream miles can decrease opportunities for fishing, swimming, and boating by decreasing fish populations, decreasing stream flow, and increasing pollution.

Table 4.3-36 illustrates the projected changes to forest and stream miles based on anticipated coal production under each of the Action Alternatives and for each coal region, as initially presented in Sections 4.2.1 and 4.2.2, respectively. These estimates provide an additional point of reference for the summary of impacts in the following subsection.

Table 4.3-36. Projected Average Annual Effects of the Action Alternatives on Forest Acreage and Stream Miles, Compared to the No Action Alternative

Coal Region	Affected Recreational Resource	Alt. 2	Alt. 3	Alt. 4	Alt. 5	Alt. 6	Alt. 7	Alt. 8	Alt. 9
Appalachian Basin	Forest[1]	1,025	1,359	1,322	1,322	5	1,322	1,320	0
Appalachian Basin	Stream[2]	184	175	180	180	179	165	180	0

Source: Adapted from results presented in Tables 4.2-10 thru 4.2-13 and Tables 4.2-19 and 4.2-20 in Sections 4.2.1 (Water Resources) and 4.2.2 (Biological Resources), respectively.
[1]Forest refers to acres of forest preserved or improved on an annual basis.
[2]Stream refers to perennial, intermittent, and ephemeral stream miles not filled, ephemeral stream miles restored, and downstream perennial, intermittent, and ephemeral stream miles preserved or improved on an annual basis.

4.3.3.4 Summary of Effects

Table 4.3-37 summarizes the impacts to recreational resources under each of the Action Alternatives as compared to the No Action Alternative and classifies the likely impacts on recreational resources based on the considerations discussed above. For each Action Alternative and region, the expected impacts within each of the coal regions are based on relative levels of coal mining activity, relative recreational resource availability, recreational activity levels, and the extent of predicted benefits to water resources and terrestrial area vegetation. As described in Section 4.0.3, the recreation section focuses on understanding potential impacts of the Action Alternatives on land- and water-based recreational opportunities within each of the seven coal regions. These recreational activities include hunting, wildlife viewing, trail use, boating, and fishing, and occur on both public and private lands within the study area. Because the Action Alternatives generally result in minor reductions in the volume of coal anticipated to be mined, impacts are generally anticipated to be beneficial, although the EIS does not attempt to quantify recreational benefits. Impacts are generally likely to extend beyond the period of active mining (long-term). Specifically, intensity determinations were made by assuming a connection between recreational impacts and the extent of predicted benefits to water resources and terrestrial area vegetation from Action Alternatives using the following analytical categories:

- Negligible: Minimal measurable impacts (adverse or beneficial) are expected; or short term effects to a small geographic area, community or economy.
- Minor Beneficial: The action could improve local recreational opportunities but would affect relatively few users.
- Moderate Beneficial: The action could improve many recreational activities locally and in adjacent areas and could affect many users.
- Major Beneficial: The action could improve most recreational activities over a widespread area. Users could choose to pursue additional recreational activities in this area.

At the national scale, Alternative 2 is anticipated to result in Moderate Beneficial impacts to recreational activities when compared to the No Action Alternative. Alternatives 3, 4, 5, 6, 7, and 8 (Preferred) are anticipated to result in Minor Beneficial impacts to recreation. Alternative 9 is anticipated to be functionally similar to the No Action Alternative and is anticipated to result in Negligible effects on recreational activities.

At a regional scale, Major Beneficial impacts are anticipated in the Appalachian Basin region under Alternative 2. Moderate Beneficial impacts are anticipated in the Appalachian Basin region under Alternatives 3, 4, 5, 7, and 8 (Preferred) and in the Colorado Plateau region under Alternatives 2, 3, 4, 7, and 8 (Preferred). Other effects on to recreational activities are anticipated to be Minor Beneficial or Negligible at the regional scale when compared to the No Action Alternative.

4.3.3.4.1 No Action Alternative (Alternative 1)

Under the No Action Alternative, no further regulations or corrective measures in addition to those already in place would be implemented. Therefore, ongoing trends in recreation would continue. Specifically, coal mining may negatively impact recreational resources and the activities they support through disruption of terrestrial and aquatic ecosystems. The nature of these impacts is described in Section 4.3.3.1 above. The annual quantity of coal demanded and associated production is anticipated to be approximately 10 percent lower in 2040 than in 2020 without implementation of the Alternatives (i.e., under the No Action Alternative). This reduction in production would reduce adverse impacts of ongoing coal mining activities on recreational activities under the No Action Alternative.

Recreational activities, including hunting, wildlife viewing, trail use, boating, and fishing, may occur on both public and private lands within the study area. Public lands, including federal, state, and locally managed lands, are often popular destinations for recreators due to the relatively natural and undeveloped quality of those lands. In addition, private lands are also used for recreation. The Illinois Basin and Appalachian Basins have the highest percent of the study protected in federal, state, local, or private conservation areas 24 and 18 percent of land area protected respectively. The states intersecting the coal regions with the highest visitation rates in terms of hunting, fishing, and wildlife viewing days were Indiana and Pennsylvania.

Future reductions in production may allow for or encourage increases in recreational activities, as well as increase the relative value that is placed on recreation activities as the quality of natural land may improve. In concert with the above, efforts to improve recreation conditions under the CWA, Wild and Scenic Rivers Act Forest Service Manual, National Wildlife Refuge System Administration Act, National Trail Systems Act, as well as regional, state, local recreation improvement efforts, may continue to improve conditions in localized areas related to causes such as park management and water quality under the No Action Alternative.

The following summaries of the Alternatives 2 through 9 describe impacts relative to the No Action Alternative.

4.3.3.4.2 Alternative 2

Alternative 2 incorporates many elements that provide relatively extensive protection of recreational resources such as forests and streams. For example, Alternative 2 prohibits all mining activities within 100 feet of perennial streams; prohibits filling of perennial streams; eliminates AOC variances; specifies fish and wildlife enhancement metrics; and establishes a 100-foot streamside vegetative corridor for all streams. While fewer acres are categorized as improved under Alternative 2 compared with Alternatives 3, 4, 5, 7, and 8 (Preferred), Alternative 2 generates the greatest extent of preserved forest benefits compared with all other Action Alternatives. Preserved forest refers to natural forest landscapes that are untouched by mining and therefore the quantity and quality of recreational opportunities are uninterrupted by mining activity. The preserved acres therefore provide greater benefit to recreational activities than the improved acres, which refers to forest that is cut for the purposes of mining and then reforested. Recreational opportunities on improved acres may be reduced or of lesser quality until the restored forest matures. High levels of recreational activity and high values placed on such activity in the Appalachian Basin region suggest a Major Beneficial impact in that region. In regions where level of recreational activity and the associated value of this activity are lower, either Moderate Beneficial (in the case of Colorado Plateau) or Minor Beneficial (in the case of Gulf Coast and Illinois Basin) effects are expected. In regions where the elements do not directly influence recreational resources, the impacts are likely Negligible.

4.3.3.4.3 Alternative 3

Alternative 3 has the potential for greater protection of forests and streams than the No Action Alternative but does not deliver protection to the same extent as Alternative 2. For instance, Alternative 3 has less explicit stream restoration requirements and allows mining through streams under certain conditions. For coal regions in which recreational activities are highly valued and activity is extensive, the predicted impact is Moderate Beneficial. For regions where activities have less value and occur with less frequency (Gulf Coast and Illinois Basin), the effects are classified as Minor Beneficial. Negligible effects are anticipated for the coal regions where Alternative 3 provisions suggest minimal change in forest or river protection.

4.3.3.4.4 Alternative 4

Alternative 4 is very similar to Alternative 3 in terms of the level of protection afforded to forests and streams. As such, the findings under Alternative 4 are identical to those for Alternative 3, described above.

4.3.3.4.5 Alternative 5

By definition, Alternative 5 has little effect on any coal region other than the Appalachian Basin. As such, the predicted impacts for the other six regions are Negligible. For the Appalachian Basin region, however, the anticipated level of recreational resource protection coupled with the high values placed on recreational activity in this region result in predicted effects that are Moderate Beneficial.

4.3.3.4.6 Alternative 6

Like Alternative 5, Alternative 6 primarily affects the Appalachian Basin region. The findings are similar to those described above for Alternative 5, except that the level of protection of the recreational resources is somewhat lower than that predicted under Alternative 5. In particular, reforestation requirements under Alternative 6 are less extensive than those under Alternative 5. As such, the predicted impact relative to the No Action Alternative is Minor Beneficial.

4.3.3.4.7 Alternative 7

Alternative 7 requirements apply only under enhanced permitting conditions. As such, it results in non-negligible protective measures for forests and streams for only three coal regions: Appalachian Basin, Colorado Plateau, and Gulf Coast. Combined with the relative extent of recreational resources and the estimated value of recreational activities in these regions, the expected impacts are Moderate Beneficial (for the Appalachian Basin and Colorado Plateau) or Minor Beneficial (for the Gulf Coast).

4.3.3.4.8 Alternative 8 (Preferred)

Alternative 8 (Preferred) offers forest and water quality protections similar to Alternatives 3 and 4. As such, it is classified as having Moderate Beneficial impacts in the Appalachian Basin and Colorado Plateau, and Minor Beneficial impacts in the Illinois Basin and Gulf Coast regions. Impacts in other regions are classified as Negligible.

4.3.3.4.9 Alternative 9

Alternative 9 would require the repromulgation of the currently vacated 2008 Stream Buffer Zone rule. This Alternative would require minimization of excess spoil generation, place limits on excess spoil fill capacity to match the anticipated amount of excess spoil to be generated, and prohibit mining activities in or within 100 feet of an intermittent or perennial stream unless the applicant demonstrates and the regulatory authority finds that avoidance is not reasonably possible. The model mines analysis indicates that the impacts of Alternative 9 would not differ significantly from those of the No Action Alternative because the Clean Water Act requirements and policies discussed in the Regulatory Impact Analysis for this rulemaking and the state AOC and excess spoil policies identified in Section 4.2.3.1 of this FEIS have effectively achieved implementation of this Alternative in Central Appalachia, which is the region in which the 2008 Stream Buffer Zone rule would have had its greatest impact if it had remained in effect. Therefore, if repromulgated, Alternative 9 would now have Negligible effects on recreation.

Table 4.3-38 summarizes the impacts of the Action Alternatives on recreational resources.

4.3.3.5 Potential Minimization and Mitigation Measures

The Action Alternatives are not expected to result in adverse environmental consequences in the context of recreational resources. Therefore, identifying potential minimization and mitigation measures is inapplicable for this analysis.

Table 4.3-38. Summary of Impacts of the Action Alternatives on Recreational Resources Compared to the No Action Alternative

Coal Region	Alt. 2	Alt. 3	Alt. 4	Alt. 5	Alt. 6	Alt. 7	Alt. 8	Alt. 9
Appalachian Basin	Major Beneficial	Moderate Beneficial	Moderate Beneficial	Moderate Beneficial	Minor Beneficial	Moderate Beneficial	Moderate Beneficial	Negligible
Colorado Plateau	Moderate Beneficial	Moderate Beneficial	Moderate Beneficial	Negligible	Negligible	Moderate Beneficial	Moderate Beneficial	Negligible
Gulf Coast	Minor Beneficial	Minor Beneficial	Minor Beneficial	Negligible	Negligible	Minor Beneficial	Minor Beneficial	Negligible
Illinois Basin	Minor Beneficial	Minor Beneficial	Minor Beneficial	Negligible	Negligible	Negligible	Minor Beneficial	Negligible
Northern Rocky Mountains and Great Plains	Negligible	Negligible	Negligible	Negligible	Negligible	Negligible	Negligible	Negligible
Northwest	Negligible	Negligible	Negligible	Negligible	Negligible	Negligible	Negligible	Negligible
Western Interior	Negligible	Negligible	Negligible	Negligible	Negligible	Negligible	Negligible	Negligible
National	Moderate Beneficial	Minor Beneficial	Minor Beneficial	Minor Beneficial	Minor Beneficial	Minor Beneficial	Minor Beneficial	Negligible

Note: Please see Table 4.0-1 for a definition of Negligible, Minor, and Moderate impact terms used above. These impact categories consider the length of impact, geographic scope of impact, available resources to impact, and potential for offsetting the impact.

4.3.4 Public Health and Safety

This section characterizes the impacts to public health and safety under each Action Alternative when compared to the No Action Alternative. The discussion is organized as follows:

- The first subsection discusses the existing regulatory environment relevant to public health and safety under the No Action Alternative;
- The second subsection identifies how key elements of the Action Alternatives could influence health and safety;
- The discussion then reviews qualitative information characterizing health and safety impacts of air and water quality changes, both for miners and for the general public; and
- The final subsection summarizes the overall impacts of each Action Alternative on health and safety.

4.3.4.1 Effects of the Current Regulatory Environment (the No Action Alternative)

Many naturally occurring trace elements can be mobilized during the surface mining process. If not adequately controlled, these trace elements can be released into surface water and groundwater (Water Resources sections of Chapters 3 and 4). Over the past few years, several studies about the relationship between mining operations in West Virginia and the health of nearby residents have been published in peer-reviewed journals. The results of these studies suggest an association between living near mining operations and increased risk of illness and premature death. To better understand the potential implications of these studies, OSMRE has requested that the National Academy of Sciences review this literature.

Studies conducted to date indicate that damage from pollutants released by surface mining persists for decades (Bernhardt and Palmer, 2011; Lindberg, et al., 2011; Palmer, et al., 2010; Pond, et al., 2008). Key elements may include, but are not limited to, iron, aluminum, nickel, copper, manganese, selenium, arsenic, lead, mercury, cadmium, beryllium, potassium, calcium, magnesium, lithium, rubidium, uranium, and strontium (Lindberg, et al., 2011; Pumure, et al., 2010; Palmer, et al., 2010; West Virginia Geological and Economic Survey (WVGES), 2012). The level of contamination in surface waters downstream of coal mining activity depends on site-specific factors, such as the composition of parent rock, interactions between elements, presence of other pollutants associated with mine runoff (e.g., sulfates (SO_4)), and other physicochemical characteristics of the site such as pH or total organic carbon (TOC) content (Pumure, et al., 2010; Hopkins, et al., 2013).

Coal mining can also introduce pollutants into the air through removal of parent rock and subsequent generation of ambient particulate matter (PM) (Aneja, et al., 2012; Ahern, et al., 2011; Hendryx, 2009). A substantial literature base indicates that increases in ambient PM concentrations (from any source) can adversely affect the health of nearby residents (U.S. EPA, 2009c).

Humans may be exposed to coal mining-related pollutants through several different exposure pathways. For example, after they have been mobilized into air, surface water or groundwater, pollutants can be transported to nearby sources of drinking water and air in residential areas, leading to potential ingestion exposure to pollutants dissolved in water and inhalation exposure to contaminated particles in air.

4.3.4.1.1 Health Impacts of Mining-Related Water Quality Changes

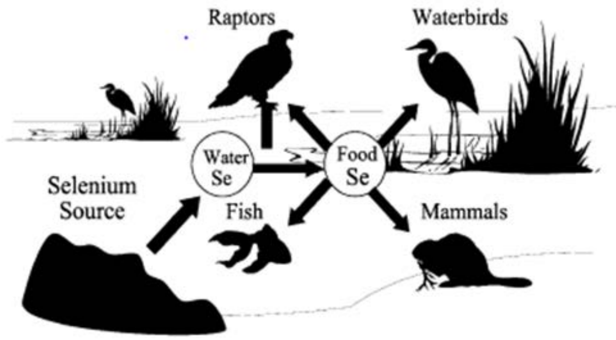
The discussion below examines how mining-related water pollution may potentially affect human health under the No Action Alternative. The discussion first focuses on the example of selenium. It begins by considering the fate and transport of selenium in the environment, illustrating how the risk posed by certain pollutants can magnify over time in the aquatic environment. The discussion also considers specific health effects associated with selenium exposure. Subsequent subsections consider risks posed by other pollutants such as sulfates and arsenic.

4.3.4.1.1.1 Effects of Selenium on Public Health

4.3.4.1.1.1.1.1 Fate and Transport of Selenium

Selenium represents a potential human health hazard around coal mines because of its persistence in the environment. Once in the aquatic environment, some coal mining-related selenium can quickly build up (bioaccumulate) and reach levels that are toxic to fish and wildlife (see Figure 4.3-8) (Lemly, 2004; Presser, 2013; Presser and Luoma, 2010). Because of bioaccumulation, even a low concentration of selenium in water has the potential to increase by several orders of magnitude in fish and wildlife (Lemly, 2008; Presser, 2013). This poses additional risk to recreational or subsistence anglers who may consume fish from contaminated waters. A 2011 U.S. EPA report on the effects of surface mining in Appalachia lists elevated selenium concentrations (to levels that are sufficient to cause toxic effects in fish and birds) as one of its major findings (U.S. EPA, 2011b).

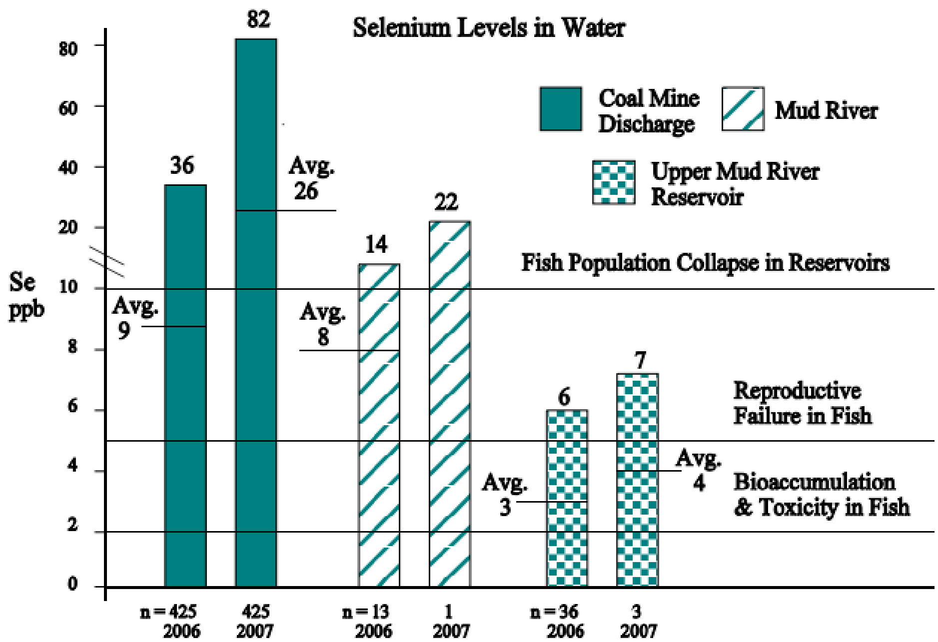
Figure 4.3-8. Bioaccumulation pathway of Selenium



Source: Lemly 2004, pg. 45.

The most extensive research on selenium and coal mining has been conducted in West Virginia. In 2007, the West Virginia Department of Environmental Protection (WVDEP) initiated an aquatic monitoring program as a result of frequent violations of EPA's 1999 and recently revised 2016 surface water quality criterion for aquatic life for selenium (U.S. EPA, 2016, WVDEP 2007a). The program is aimed at evaluating the extent and severity of pollution from coal mining (WVDEP, 2007b). This water quality monitoring was conducted as part of mine wastewater discharge permit requirements under the U.S. EPA's National Pollutant Discharge Elimination System (NPDES). Results of this effort in the Mud River watershed in West Virginia indicated that selenium levels in samples of water, fish tissue, and invertebrate food organisms exceeded toxic thresholds for fish (see Figure 4.3-9) (Lemly, 2008).

Figure 4.3-9. Selenium concentrations (µg/L or parts-per-billion) measured in coal mine discharges and surface waters of the Mud River ecosystem, West Virginia, relative to levels that can bioaccumulate and become toxic to fish.

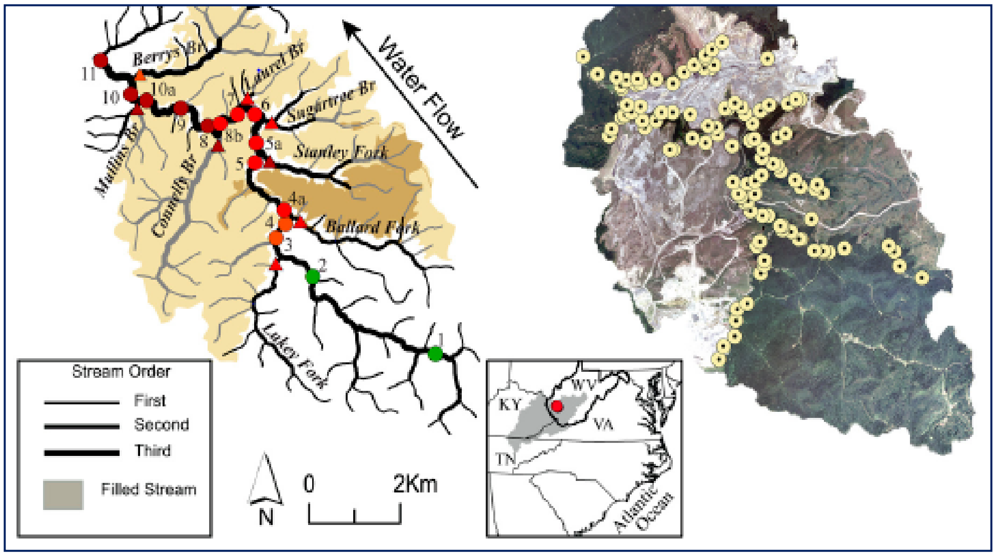


Source: Lemly, 2008, pg. 173.

The monitoring conducted by WVDEP suggests that coal mining can lead to human exposure to selenium through fish ingestion. State advisories are in effect for excessive human consumption of fish from waters downstream of coal mining activities in some areas of West Virginia (Palmer, et al., 2010). The 2012 sport fish consumption advisory press release for West Virginia states that “Low levels of chemicals like PCBs, mercury, selenium and dioxin have been found in some fish from certain waters” (WVDHHR, 2012b). The document “West Virginia Fish Consumption Advisories Available for 2012” indicates that measurable levels of selenium were detected in samples from water bodies that include Upper Mud Lake and Pinnacle Creek (WVDHHR, 2012b), both of which are in watersheds that are heavily mined. Although these state advisories are in effect, exposure through fish consumption may still occur if anglers are unaware of or disregard the advisories.

There are additional studies that have found toxic levels of selenium in surface water near coal mining areas. In 2011, Lindberg, et al. published a study of selenium levels along the Upper Mud River and its tributaries (see Figure 4.3-10). The headwaters of the Mud River begin in Boone County, West Virginia, and flow northwest into Lincoln County to the Mud River Reservoir, approximately 25 km downstream. By the time the Upper Mud River exits the active surface mining area following its confluence with Berry’s Branch, it has received mining effluent from eight tributaries that contain 68 NPDES permitted discharge points, all of which are for coal mining activities.

Figure 4.3-10. Map of study area depicting Upper Mud River and associated tributaries with aerial photo on right

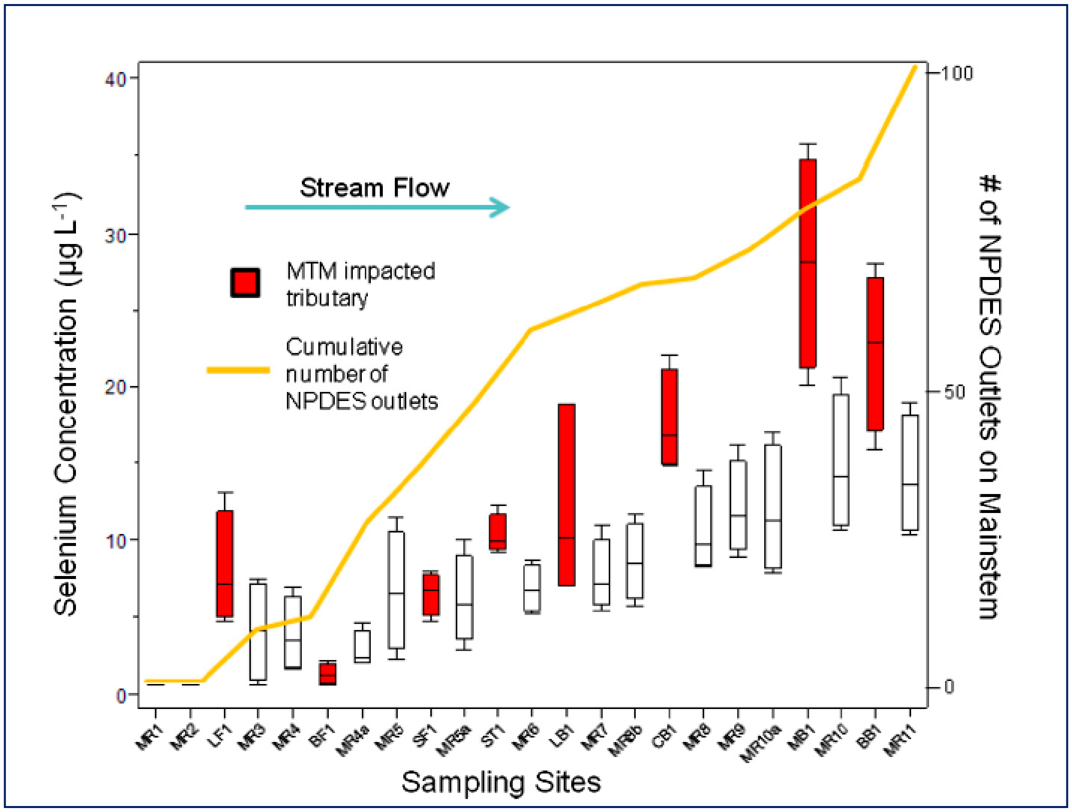


Note: Sampling sites consisted of 15 mainstream (circles) and eight named tributary locations (triangles). Sites 1 and 2 were located upstream of current and historic coal mining activity. The remaining sites were chosen so as to bracket each confluence of the Upper Mud River and a tributary affected by coal mining. Aerial photo on right shows location of 105 active surface-mining-related outlets within the watershed that are regulated through eight NPDES permits.

Source: Lindberg et al. 2011, Figure 1, p. 2.

Prior to the initiation of surface coal mining in the Lukey Fork watershed, EPA water quality data (see Figure 4.3-11) recorded no detectable selenium in the stream (EPA detection limit of 3.0 μgL^{-1}). During the Lindberg, et al. (2011) study, however, selenium concentrations were found in Lukey Fork at levels up to 13.1 μgL^{-1} (see Figure 4.3-11). Additional coal mining-impacted tributaries further contributed to selenium contamination, and downstream of the confluence with Berry Branch, selenium concentrations averaged 14.1 μgL^{-1}. The investigators measured selenium concentrations of 6.5 and 4.0 μgL^{-1} in samples taken in September and December of 2010 from an area well below the Hobet mine complex, despite the fact that surface water at that point receives input from multiple unmined tributaries (including the Left Branch of the Mud River) (Lindberg, 2011, p. 4).

Figure 4.3-11. Box plot showing range and mean stream selenium concentrations during four surveys in 2010 on the Upper Mud River



Note: The cumulative number of active NPDES permitted outlets is represented by a yellow line with the scale on the right side of the graph. The red box plots denote the selenium concentrations for coal mining-impacted tributaries, with the remainder representing mainstream sampling sites.

Source: Lindberg et al. 2011, Figure S4, p. S2.

A study published by USGS in 2006, entitled "Ground-Water Quality in Unmined Areas and Near Reclaimed Surface Coal Mines in the Northern and Central Appalachian Coal regions, Pennsylvania and West Virginia" (McAuley and Kozar, 2006), provides additional evidence of long-lasting adverse impacts on water quality in surface coal mining areas. This study examined the transport of selenium generated during surface mining activity, and found that under the current regulations, even after mine-site reclamation, groundwater samples from domestic supply wells have higher levels of mine-derived chemical constituents than well water from unmined areas (McAuley and Kozar, 2006). A study published in 2012 sampled the groundwater in 58 wells and springs in West Virginia. The study found elevated levels of selenium in general, and three of the samples tested exceeded EPA's 1999 and 2016 surface water quality selenium criteria for aquatic life (U.S. EPA, 2016, Brantley, 2012). A number of additional studies that sampled drinking water supplies found metals, including selenium, in domestic wells in coal mining areas at levels that pose human health concerns (groundwater and drinking water concentrations exceeding the EPA standard of 50 μgL^{-1}) (Wigginton, et al., 2008;; Stout and Papillo, 2004).

4.3.4.1.1.1.1.2 Effects on Public Health

Although selenium is an essential nutrient for humans, it can have toxic effects as dosage increases. Excessive intake of selenium can result in a condition called selenosis. Clinical signs of selenosis include a characteristic "garlic odor" of excess selenium excretion in the breath and urine, thickened and brittle nails, hair and nail loss, lowered hemoglobin levels, mottled teeth, skin lesions and central nervous system abnormalities (e.g., peripheral anesthesia and pain in the extremities) (ATSDR, 2003; U.S. EPA, 1991). A recent study of patients with colorectal polyps also identified a significantly higher concentration of selenium in polyp versus control tissue (Alimonti, et al., 2008).

While intake levels may not be representative of U.S. populations, studies of populations in China living in an area with naturally occurring but unusually high environmental concentrations of selenium found that "chronic dietary exposure to excess levels of selenium has been associated with diseased nails and skin and hair loss, as well neurological problems, including unsteady gait and paralysis" (ATSDR, 2003, pg. 15). In 1989, Yang et al. conducted a follow-up study in these areas of China (three geographical areas with low, medium and high selenium levels in the soil and food supply were chosen for comparison). The investigators found that selenium "levels in soil and approximately 30 typical food types commonly eaten by the exposed population demonstrated a positive correlation with blood and tissue selenium levels" (U.S. EPA, 1991). Selenium concentrations of various tissues were associated with alterations in biochemical parameters that are indicative of possible selenium- induced liver dysfunction, as well as clinical signs of selenosis (U.S. EPA, 1991).

According to ATSDR's toxicological profile of selenium, "some evidence for effects on the endocrine system in humans and rats has also been found following long-term oral exposure to elevated levels of dietary selenium" (ATSDR, 2003). These studies suggest that subsistence anglers and recreational anglers who frequently consume fish from contaminated areas could potentially be at risk from excessive ingestion of selenium.

4.3.4.1.1.2 Effects of Sulfates on Public Health

In recent decades, policymakers have expressed concern over the buildup of sulfates in streams as a result of surface coal mining. The oxidation of pyrite or other iron-sulfide minerals with water yields sulfuric acid, which can increase stream acidity if coal mine drainage is not buffered by stream alkalinity. This drainage from coal mines, also called acid mine drainage (AMD), can contribute to the degradation of streams in coal regions, affecting both drinking and industrial water. Acid mine drainage in streams can also result in increased levels of sulfates and total dissolved solids, in addition to potentially lowered pH, in stream water. An increase in the acidity of stream water may consequently result in higher concentrations of zinc, aluminum, and manganese though mineralization (USGS, 2000c).

Elevated stream water acidity may adversely impact public health in historic coal mining regions. For example in the Appalachian region, Williams et al. (1996) collected water samples from 270 mine discharges in the Stonycreek River Basin (Pennsylvania), and found high concentrations of aluminum and sulfates; many of the samples had pH levels less than 3.0, which is sufficiently acidic to cause irritation to skin and eyes (WHO, 2003). The health effects of elevated levels of sulfates in drinking water have not been extensively studied. The primary effect of increased sulfates in drinking water is an increase in diarrhea, particularly in infants and transients. EPA conducted a study that measured the impact of high sulfate levels on infants and pregnant women and found a weak increase in reports of diarrhea with higher doses of sulfate in drinking water. Further, WHO conducted a survey in North Dakota and found a slight increase in the percentage of people who had a laxative effect with water containing 500-1000 mg/L of sulfate (28 percent of those surveyed) as compared to those exposed to drinking water containing less than 500 mg/L of sulfate (21 percent of those surveyed). For both studies, the researchers were unable to identify a sulfate concentration in drinking water that leads to serious human health effects (WHO, 2004).

4.3.4.1.1.3 Effects of Arsenic on Public Health

Surface mining has resulted in elevated levels of arsenic in drinking water in coal mining areas. Arsenic is a mineral that occurs naturally in rocks and coal. Similar to the occurrence of sulfuric acid in stream water, the major source of arsenic is pyrite, which is composed of iron and sulfur. Data collected by the USGS suggest that the average arsenic concentration for U.S. coal is approximately 24 parts per million (USGS, 2005b). High levels of arsenic may affect public health, and this problem has been most prevalent in domestic well waters. Studies have demonstrated that inorganic arsenic in drinking water may play a significant role in cancers, primarily bladder cancers (Borak, 2007; Shiber, 2005). Shiber (2005) measured the various levels of arsenic in domestic water in the Central Appalachian region, citing coal mining as the major source. The results of this study indicate that over half of the samples collected from tap water in the region contain one part per billion (ppb) or more of arsenic, an amount that is greater than the standards for many other carcinogens found in drinking water. Of the 13 counties studied in Kentucky, the average arsenic level was found to be approximately 2.99 ppb (Shiber, 2005), which is within EPA drinking water guidelines. The National Research Council's 2001 report to EPA reported that the lifetime risk of bladder and lung cancer from water arsenic exposure at three ppb is one in 1,000 (Shiber, 2005).

It is possible that some areas may experience reductions in arsenic exposure in drinking water as coal production decreases. Although public tap water is regulated for arsenic concentrations, users of private wells may benefit from reductions in arsenic concentrations. Chapter 3.5.3 reports the percentage of private well users in each of the coal regions, but proximity of these sources to coal production is not examined. However, any decrease in the concentration of arsenic in private wells may decrease lifetime risks of bladder and lung cancer for well water consumers.

4.3.4.1.1.4 Other Evidence of Potential Public Health Effects of Surface Mining

There is a small but growing body of epidemiological research that suggests an association between adverse health effects and proximity of residence to a coal mining region in the Appalachian Basin. Hendryx, et al. (2008) studied the elevated rates of cancer mortality in the coal mining regions in Appalachia and found that, after controlling for socioeconomic factors including education, smoking rates, and poverty, coal mining in Appalachia was associated with elevated rates of cancer mortality. In a study published in 2010, Hitt and Hendryx extended the work published in 2008 (Hendryx, 2008) by assessing the relationship between the ecological integrity of streams, calculated through environmental quality gradients, and human cancer incidence. The 2010 study found a statistically significant inverse relationship between ecological integrity of streams and mortality rates from certain types of cancer (digestive, breast, respiratory and urinary), and a positive correlation between coal mining intensity and rates of certain types of cancer, including respiratory cancer (Hitt and Hendryx, 2010). In 2010, a cross-sectional retrospective analysis of mothers in West Virginia found that residence in coal mining areas posed a risk of low birth weight, even after controlling for level of coal mining, mother's age, marriage status, drinking during pregnancy, smoking during pregnancy, medical risk, years of education, late prenatal care, no prenatal care, and number of previous pregnancies (Ahern, et al., 2010). A separate 2010 study showed that "proficiency rates for schools in coal-mining counties versus non-coal mining counties were significantly lower in all subject areas . . . and remained significantly lower ($p < 0.0008$ or better) after adjusting for county high school education rates, percent of low-income students, percent of highly qualified teachers, number of students tested, and county smoking rates" (Cain and Hendryx, 2010).

A 2012 retrospective cross-sectional study of county-level cancer mortality rate data from the Center for Disease Control (CDC) compared age-adjusted cancer mortality rates in Central Appalachian mountaintop mining counties versus Central Appalachian counties with other types of mining and counties with no mining.[64] After controlling for covariates, the study found that lung cancer mortality rates were significantly associated with the presence of mountaintop mining in a community. The study also found evidence that mortality from leukemia, lung, bladder, and colorectal cancer were higher in mountaintop-mining areas compared to other mining areas, although the associations were not statistically significant. The magnitude of the association between mountaintop mining activity and cancer mortality was greater in more recent years (Ahern and Hendryx, 2012), suggesting that some adverse health effects may observed be until years after exposure. In a 2011 retrospective analysis of 2006 self-reported data on health-related quality of life indicators, residents of mountaintop mining communities in Appalachia reported significantly more days of poor physical, mental, and activity limitation and poorer self-rated health, when compared to residents of counties with other types of coal mining and to residents of non-mining counties (Zullig and Hendryx, 2011). Other recent epidemiological studies have also found associations between adverse health effects (such as increased incidence of birth defects and increased adult mortality from cancer, heart, respiratory, and kidney disease) and residence in coal mining counties in Appalachia, after controlling for other risk factors (Ahern, et al., 2011; Esch and Hendryx, 2011; Hendryx, et al., 2010; Hendryx, 2009; Hendryx and Ahern, 2009; Hendryx and Ahern, 2008).

Although these studies do not control for occupational exposure, the authors assert that because they have found positive associations in both men and women between proximity to mining operations and adverse health impacts, the effects are not strictly due to direct occupational exposure of coal miners, who are predominantly male (Ahern, et al., 2010; Hendryx, 2009; Hendryx and Ahern, 2008). This assertion is supported by a U.S. Department of Labor 2011 report which states that of the 94,000 people employed by the coal mining industry in 2010, only six percent were women (U.S. BLS, 2011b).

A retrospective study by Borak et al., highlights the complexity of disentangling causal relationships in an environment where economic factors impact the health of residents (Borak et al. 2012). This study, which looked at all-cause mortality rates for residents of Appalachia during the years 2000 to 2004, found that coal mining was not per se an independent risk factor for increased mortality in Appalachia. The authors found that increased mortality was significantly associated with greater poverty, lower median household income, fewer high school graduates, rural location, obesity rate, and demographic factors

---

[64] Mountaintop Mining (MTM) is defined as a surface mining site crossing a ridge or mountain peak, and either (a) spanning a minimum of 210 acres including 40 acres of removed ridge top, or (b) spanning 40 to 320 acres and containing a minimum of 10 to 40 acres of ridge top.

including sex and race. Lower college graduate rate was nearly significant, but no significant associations were found for coal mining, smoking, physician supply, and diabetes.

Studies conducted to date attempt to control for other risk factors but more rigorous epidemiological studies are required to investigate these associations (e.g., long term prospective cohort follow up studies). In general, epidemiological studies are limited in their ability to prove a causal relationship, but continued positive findings obtained through a variety of study designs can provide a substantial weight of evidence in support of a causal relationship. The current body of evidence, while it does not reach that level, does suggest that further research on impacts of coal mining operations on nearby residents is warranted.

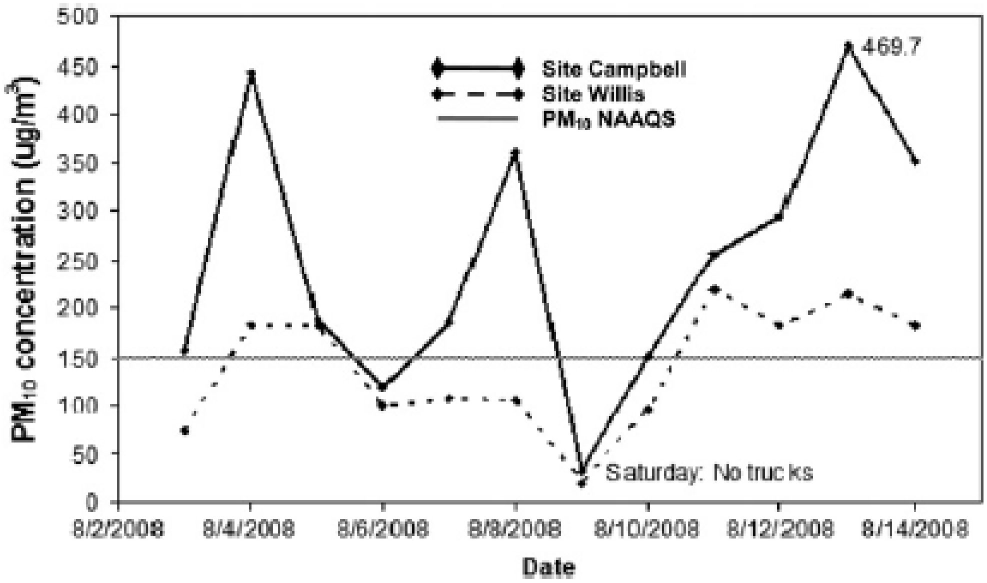
4.3.4.1.2 Health Effects of Mining-Related Air Quality Changes

Less empirical evidence is available with respect to the effects of coal mining on air quality, although this topic is a focus of current research. One recently published study of surface coal mining in the Appalachian Basin provides quantitative evidence of adverse effects on air quality in residential areas. The study was done in Roda, Virginia, in close proximity to surface coal mining operations where residents reported a high volume of truck traffic and significant dust problems (Aneja, et al., 2012). In August 2008, for a period of twelve days, two PM_{10} (i.e., particulate matter with particle size of ten micrometers or less) air samplers were placed on residential properties located near a road that terminates at the entrances to several mines.[65] The sites were selected to be representative of exposure for local residents. One residence, ("Site Campbell") was located very close to the entrance to the coal mines, and the other, ("Site Willis") was located one mile away. Results of this study suggest that residents of Roda may frequently be exposed to PM_{10} concentrations that exceed EPA's 24-hour health-based national ambient air quality standard (Figure 4.3-12).

Analysis of the composition of the air samples in this study identified the presence of antimony, arsenic, beryllium, cadmium, chromium, cobalt, lead, manganese, mercury, nickel, and selenium, which are all known components of coal. While ambient background concentrations of selenium in the air were below 10 ng/m^3 (ASTDR, 2003), Aneja, et al. (2012) found levels five to six times higher. These data indicate that activities related to the coal mines are a major contributor to the local air pollution, and that this is likely a chronic problem not only for Roda, but for other similarly situated Appalachian Basin communities.

[65] Inhalation of small particulates like PM_{10} is hazardous because the particles can transport toxins that lodge deep in the lung tissue. Studies have linked particulate exposure to premature mortality (especially in individuals with pre-existing heart or lung disease), heart problems, asthma, and other respiratory conditions (U.S. EPA, 2014f).

Figure 4.3-12. Measurements of PM10 24-h concentration at two locations (Site Campbell and Site Willis) in Roda, Virginia, during August 2008.



Source: Aneja et al., 2012, Figure 2, p. 498.

Studies of mining practices in other countries also indicate that levels of particulate matter released from surface mines are greater than those released from underground mining operations. Consequently, in addition to occupational exposure to miners, community-level exposure to increased particulate matter concentrations may occur as a result of increased surface coal mining activity (Ghose and Majee, 2007; Ghose, 2007). Under Alternative 2, there would be a shift from surface mining to underground mining, adverse public health effects from poor air quality resulting from coal mining activity could potentially be reduced on a community level.

Due to anticipated decreases in production levels as a result of the Action Alternatives, air quality for adjacent communities may improve due to a lower overall exposure to coal dust and particulate matter. Underground mining, however, exposes miners to large amounts of coal dust and may have adverse health effects on miners where production methods shift from surface to underground. Extensive exposure to dust may increase miners' risk to various malignant and nonmalignant lung and bladder diseases. A common and well-documented disease, coal workers' pneumoconiosis, is largely caused by exposure to coal dust. The components of coal dust may include various carcinogenic organic and inorganic compounds, including chrysene, benzo(a)pyrene, and silica (Swaen, et al., 1995). These impacts are discussed further below.

4.3.4.1.2.1 Nonmalignant Lung Diseases

While not apparent in overall production forecasts developed for this FEIS, any shift of extraction methods from surface to underground mining in the Appalachian Basin region may increase the risk of disease and lung cancer for miners due to elevated exposure to carcinogenic coal dust. Kuempel, et al. (1995) studied the quantitative relationship between exposure to coal mine dust and mortality from nonmalignant respiratory disease and found that miners who were exposed for a working lifetime to dust levels below the U.S. standard of two milligrams per cubic meter (mg/m^3) are subject to a greater risk of dying from pneumoconiosis, chronic bronchitis, or emphysema. Of the 8,878 miners medically examined from 1969 to 1971 in Kuempel, et al.'s 1995 study, approximately 207 died from pneumoconiosis and 76 died from chronic bronchitis or emphysema. Kuempel, et al.'s 1995 study results show an upper-bound death rate of approximately 1.16 percent from pneumoconiosis, and 0.43 percent from chronic bronchitis or emphysema per year for miners on average. The study calculated lower-bound death rates of 0.087 percent from pneumoconiosis, and 0.012 percent from bronchitis or emphysema. Of note, however, this study relies on miners' exposure and respiratory illnesses from more than four decades ago. Subsequent regulations focused on miner safety may have since reduced the calculated rates.

4.3.4.1.2.2 Lung Cancer

Prolonged exposure to dust particles increases cancer risks for miners. Many studies have demonstrated that poorly soluble particles of low toxicity (such as coal mine dust) have caused lung cancer in rats (Borm, et al., 2004). Although these studies are not conclusive regarding the susceptibility of humans to lung cancer as a result of prolonged exposure to coal dust, there is concern over this issue, especially for underground mining. It is currently difficult to quantify the exact impact of changes in production level or mine type on the risk of lung cancer, however. This is due to the lack of data on the differences in coal mine dust exposure for underground and surface mines, as well as the lack of a clear relationship between production level and dust exposure.

4.3.4.1.2.3 Gastric Cancer

Studies have also explored the relationship between gastric health and underground coal mining. The coal dust to which underground miners are exposed may contain carcinogenic elements and these compounds may enter the miners' digestive systems. The coal dust may interact with agents in the acidic environment of the stomach, such as nitrite, to form mutagenic compounds (Swaen, et al., 1995). Swaen, et al. (1995) studied a sample of 3,790 coal miners that had abnormal chest x-ray films (suggesting pneumoconiosis) and found that deaths from gastric cancer were higher than expected, at 120 deaths. The fatality rate of pneumoconiotic coal miners due to gastric cancer resulted in a standardized mortality ratio of 147.5 (point estimate). Overall, their results suggest that pneumoconiotic coal miners have an approximately 22.5 percent to 76.3 percent higher gastric cancer fatality rate than the general population.

4.3.4.1.2.4 Other Public Health Effects

Coal mining contributes to greenhouse gas emission levels and releases large amounts of coal dust particles into the air. The release of particulates and other emissions that deteriorate ambient air quality may affect public health. As underground mining contains (i.e., controls) most of the dust particle byproducts from mining, one possible consequence of a shift in surface mining to underground mining is a decrease in dust release.

Hendryx and Ahern (2008) found that residential proximity to coal mining areas was associated with a higher risk for hypertension, kidney disease, chronic lung disease, and cardiopulmonary disease. Previous studies have found that exposure to coal byproducts is linked to kidney disease and hypertension (Hendryx and Ahern, 2008). While the study highlights the potential for public health impacts with increases in coal production volume in the future, it does not establish a clear causal relationship between coal production and these health effects. Studies of mining practices in other countries, however, indicate that levels of particulate matter released from surface mines are higher than those released from underground mining operations. Consequently, in addition to occupational exposure to miners, community-level exposure to increased particulate matter concentrations may occur as a result of increased surface coal mining activity (Ghose, 2007; Ghose and Majee, 2007). With any shift from surface mining to underground mining, adverse public health effects from poor air quality resulting from coal mining activity could potentially be reduced on a community level. However, additional research addressing differences in mining practices in the U.S. versus practices in other countries would be needed to better understand the potential for health improvements related to improved air quality.

As a greenhouse gas, methane emissions contribute to the creation of ozone, potentially affecting global climate patterns. Higher methane emissions due to an increased number of underground mines or an increased level of production may also affect the air quality of surrounding communities. Both global warming and deteriorating air quality may have public health implications, as discussed in Section 4.2.4.

4.3.4.2 Action Alternatives and Potential Effects on Public Health and Safety

The Action Alternatives may yield water quality improvements relative to the No Action Alternative. Nearly all the elements of the Action Alternatives (except Alternative 9) have potential to benefit water quality, including improved baseline data and monitoring; material damage to the hydrologic balance definitions and evaluation thresholds; limitations on fill placement and mining through streams; improved reforestation; and introduction of streamside vegetative corridors. Section 4.2.1 describes all of these elements and potential benefits in greater detail. In addition, reduced coal production and shifts in the balance of surface and underground production may have coincident benefits to air quality (as described in Section 4.2.4).

4.3.4.2.1 Qualitative Analysis of Public Health and Safety Impacts

As stated above, the Action Alternatives may affect public health and safety by improving water quality and air quality relative to the No Action Alternative. Nearly all the elements of the Action Alternatives (except Alternative 9) have potential to benefit water quality, including improved baseline data and monitoring; material damage to the hydrologic balance definitions and evaluation thresholds; limitations on fill placement and mining through streams; improved reforestation; and introduction of streamside vegetative corridors. Section 4.2.1 describes all of these elements and potential benefits in greater detail. In addition, reduced coal production and shifts in the balance of surface and underground production may have coincident benefits to air quality (as described in Section 4.2.4).

The evaluation of potential impacts on public health relies on qualitative information regarding potential effects of the Action Alternatives. This analysis finds that the primary public health benefits of the Action Alternatives are associated with the expected improvements to water resources, as described in Section 4.2.1. By improving baseline monitoring, establishing evaluation thresholds to prevent damage, requiring mandatory evaluation of monitoring data, and improving techniques to better restore sites to premining conditions, the Action Alternatives may benefit water quality. In addition to benefits to individuals, these improvements in water quality may benefit public drinking water suppliers by reducing pollutant levels and therefore costs of water treatment. Ideally, this analysis would combine information on the expected water quality benefits in each region, with information on the potentially vulnerable population (e.g., exposed via the pathways described in Section 4.3.4). Absent specific information on the locations of future mines, this analysis is not able to forecast the size of the population benefitting from improved water quality via the exposure pathways described (i.e., groundwater consumption, fish and wildlife consumption, etc.). In addition to water quality benefits, the Action Alternatives may result in indirect benefits to air quality, primarily as a result of reducing coal production and subsequent coal combustion.

4.3.4.3 Summary of Effects

This section summarizes impacts to public health and safety by Action Alternative and region as compared to the No Action Alternative. Impacts are forecasted from 2020 to 2040. As described in Section 4.0, this analysis categorized impacts as either Negligible, Minor, Moderate, or Major, and either Beneficial or Adverse.

Generally, major effects are expected to result from significant changes in water quality that are persistent over the long-term, and cover a broad geographic area. Moderate effects are less significant water quality improvements that persist over the long-term but cover a more limited geographic area. Minor effects are when there are limited changes to water quality, and when these effects pertain to a limited geographic area. More specifically, as presented in Section 4.0.3, intensity determinations were made using the following analytical categories:

- Negligible: Minimal measurable impacts (adverse or beneficial) are expected; or short term effects to a small geographic area, community or economy.
- Minor Beneficial: The action could reduce 1) soil, groundwater, and/or surface water contamination; 2) exposure of contaminated media as occupational hazard; and/or 3) mobilization and migration of pollutants currently in the soil, ground water, or surface water in localized areas.
- Moderate Beneficial: The action could reduce 1) soil, groundwater, and/or surface water contamination; 2) exposure of contaminated media as occupational hazard; and/or 3) mobilization and migration of pollutants currently in the soil, ground water, or surface water in localized and adjacent areas.
- Major Beneficial: The action could reduce 1) soil, groundwater, and/or surface water contamination; 2) exposure of contaminated media as occupational hazard; and/or 3) mobilization and migration of pollutants currently in the soil, ground water, or surface water over widespread areas.

Table 4.3-39 describes the rationale used to classify the effects of each Alternative and region. Table 4.3-40 summarizes this information for overall public health and safety impacts. As identified in Table 4.3-40, at the national scale, Alternatives 2, 3, 4, and 8 (Preferred) are anticipated to result in Major Beneficial impacts to public health and safety when compared to the No Action Alternative. Alternatives 6 and 7 are anticipated to result in Moderate Beneficial impacts to public health and safety. Alternative 5 is anticipated to result in Minor Beneficial impacts to public health and safety at the national scale.

Alternative 9 is anticipated to be functionally similar to the No Action Alternative and is anticipated to result in Negligible effects on public health and safety.

At a regional scale, Major Beneficial impacts are anticipated in the Appalachian Basin and Illinois Basin regions under Alternatives 2, 3, 4, and 8 (Preferred). Major Beneficial impacts are also anticipated in the Appalachian Basin under Alternative 7. Moderate Beneficial impacts are expected in the Colorado Plateau, Gulf Coast, and Northern Rocky Mountains and Great Plains regions under Alternatives 2, 3, 4, 6, 7, and 8 (Preferred). Moderate Beneficial impacts are also anticipated in the Appalachian Basin for Alternatives 5 and 6, and in the Illinois Basin for Alternatives 6 and 7. Other effects on public health and safety are anticipated to be Minor Beneficial or Negligible at the regional scale when compared to the No Action Alternative.

The subsections below discuss each Action Alternative individually.

Table 4.3-39a. Impacts of Alternative 2 on Public Health Compared to the No Action Alternative

Regulatory Alternative and Coal Region	Impact to Public Health and Safety	Rationale
Appalachian Basin Region	Major Beneficial	• Long-term • Relatively great water quality change • Broad geographic scope
Colorado Plateau Region	Moderate Beneficial	• Long-term • Relatively moderate water quality change • Limited scope
Gulf Coast Region	Moderate Beneficial	• Long-term • Relatively moderate water quality change • Limited scope
Illinois Basin Region	Major Beneficial	• Long-term • Relatively great water quality change • Broad geographic scope
Northern Rocky Mountains and Great Plains Region	Moderate Beneficial	• Long-term • Relatively moderate water quality change • Limited scope
Northwest Region	Negligible	• Limited coal mining activity
Western Interior Region	Negligible	• Limited coal mining activity

Table 4.3-39b. Impacts of Alternative 3 on Public Health Compared to the No Action Alternative

Regulatory Alternative and Coal Region	Impact to Public Health and Safety	Rationale
Appalachian Basin Region	Major Beneficial	• Long-term • Relatively great water quality change • Broad geographic scope
Colorado Plateau Region	Moderate Beneficial	• Long-term • Relatively moderate water quality change • Limited scope
Gulf Coast Region	Moderate Beneficial	• Long-term • Relatively moderate water quality change • Limited scope
Illinois Basin Region	Major Beneficial	• Long-term • Relatively great water quality change • Broad geographic scope
Northern Rocky Mountains and Great Plains Region	Moderate Beneficial	• Long-term • Relatively moderate water quality change • Limited scope
Northwest Region	Negligible	• Limited coal mining activity
Western Interior Region	Negligible	• Limited coal mining activity

National Effect	Major Beneficial	Major Beneficial	Major Beneficial	Minor Beneficial	Moderate Beneficial	Moderate Beneficial	Major Beneficial	Negligible

Note: See Table 4.0-1 for a definition of Negligible, Minor, and Moderate impact terms used above. These impact categories consider the length of impact, geographic scope of impact, and potential for offsetting the impact.

4.3.4.3.1 Alternative 1 (No Action Alternative)

Under the No Action Alternative, no further regulations or corrective measures in addition those already in place would be implemented. Therefore, ongoing public health and safety trends would continue. The annual quantity of coal demanded and associated production is anticipated to be approximately 10 percent lower in 2040 than in 2020 without implementation of the Alternatives (i.e., under the No Action Alternative). This reduction in production would reduce adverse impacts of ongoing coal mining activities on water resources under the No Action Alternative.

Water and air quality are primary drivers of public health changes in coal mining regions. Arsenic, selenium, and sulfates are drinking water pollutants found to be elevated near mining regions. Of these pollutants, arsenic appears to be the most concerning as studies have demonstrated that inorganic arsenic in drinking water may play a significant role in cancers, primarily bladder cancers (Borak, 2007; Shiber, 2005). Surface mining has resulted in elevated levels of arsenic in drinking water in some coal mining areas. It is possible that some areas may experience reductions in arsenic exposure in drinking water as coal production decreases under the No Action Alternative. Although public tap water is regulated for arsenic concentrations, users of private wells may benefit from reductions in arsenic concentrations.

Trends in air quality under the No Action Alternative would also affect overall public health in coal mining regions. In particular, coal dust may be associated with nonmalignant lung disease, lung cancer, and gastric cancer. Additionally, coal mining contributes to rising greenhouse gas emissions, which has negative public health impacts from both ambient air quality and global warming. Due to forecasted decreases in production levels, air quality for adjacent communities may improve due to a lower overall exposure to coal dust and particulate matter.

In concert with the above, efforts to improve public health under the Federal Mine Safety and Health Act, Abandoned Mine Lands Program, state mining and water quality regulations, the CWA, as well as regional, state, local mine safety and pollution improvement efforts, may continue to improve conditions in localized areas related to causes such mining safety, drinking and surface water quality, and mine reclamation.

4.3.4.3.2 Alternative 2

As described in more detail in Section 4.2.1, Alternative 2 provides major benefits to water resources. This finding is driven by expected improvements to water resources in the Appalachian Basin, and to a slightly less extent, in the Illinois Basin. These benefits extend beyond the mine sites and are expected to persist over time due to the improved water quality management practices at the mines under Alternative 2. Absent information on the magnitude of the population benefitting from this improvement, this analysis assumes the relative effect of the Alternative on water quality (i.e., minor, moderate, major) similarly benefits public health within the region.

4.3.4.3.3 Alternative 3

For similar reasons to Alternative 2, Section 4.2.1 indicates that Alternative 3 provides major benefits to water resources, and therefore supports improvements in public health. This finding is driven by expected improvements to water resources in the Appalachian Basin, and to a slightly less extent, in the Illinois Basin. Moderate benefits are also expected in the Colorado Plateau, Gulf Coast, and Northern Rocky Mountains and Great Plains, where improvements are moderate but pertain to smaller geographic areas.

4.3.4.3.4 Alternative 4

Alternative 4 provides major benefits to water resources and, by extension, conditions to support public health improvements, in the Appalachian and the Illinois Basins. As with Alternative 3, moderate benefits are also expected in the Colorado Plateau, Gulf Coast, and Northern Rocky Mountains and Great Plains.

4.3.4.3.5 Alternative 5

Water quality benefits under Alternative 5 are likely moderate in the Appalachian Basin, due to a relatively limited geographic scope as compared with Alternatives 2, 3, and 4. This Alternative is not expected to benefit water quality (and public health) in other coal regions.

4.3.4.3.6 Alternative 6

Benefits to water resources (and public health) are Moderate Beneficial across all regions except the Northwest and Western Interior, where effects of the Alternative are Negligible.

4.3.4.3.7 Alternative 7

Impacts on water resources are beneficial and concentrated in the Appalachian Basin, consistent with the findings in Section 4.2.1. Benefits to water resources (and public health) are moderate across all other regions, except the Northwest and Western Interior where the Alternative has Negligible effects.

4.3.4.3.8 Alternative 8 (Preferred)

Alternative 8 (Preferred) provides major benefits to water resources (and public health) in the Appalachian and the Illinois Basins. As with Alternative 3, Moderate Beneficial effects are also expected in the Colorado Plateau, Gulf Coast, and Northern Rocky Mountains and Great Plains.

4.3.4.3.9 Alternative 9

Alternative 9 considers a scenario in which the 2008 Stream Buffer Zone rule is re-promulgated and fully implemented across the timeframe of this analysis. Engineering analysis of current coal industry practices finds that, during the period that the 2008 rule was in place, the permits issued in the Appalachian Basin changed in response to EPA review of Clean Water Act permits such that they serve as models for best practices for future permits. Accordingly, Alternative 9, which is effectively limited to Appalachia, would now not be expected to be functionally different than the No Action Alternative. Alternative 9 is therefore anticipated to have Negligible effects on public health and safety as evaluated in this FEIS.

4.3.4.4 Potential Minimization and Mitigation Measures

As the expected effects of the rule are generally beneficial, minimization and mitigation measures are not necessary.

4.3.5 Archaeology, Paleontology, and Cultural Resources

This section of Chapter 4 analyzes how the No Action Alternative and the Action Alternatives would affect paleontological and cultural resources. The discussion in this section is brief because none of the Action Alternatives include any proposed changes within the regulations that directly address these resources. Any effects would be indirect and would occur only as a result of effects on other resources, specifically to geology and soils, and then only if paleontological and cultural resources are present in the disturbed area. Therefore much of the subsequent discussion in this section relies on the analysis of soil and geology impacts contained in section 4.2.3 and the potential for additional effects from the proposed action is very limited.

The following content is structured as follows:

- It begins with a description of the existing regulatory environment to assist the reader in understanding the impacts of the No Action Alternative on paleontological and cultural resources.
- It concludes with a summary of the expected effects of the elements of the Action Alternatives. All effects would be Negligible so the discussion does not provide a by Alternative comparison in relation to these resources.

4.3.5.1 Effects of the Current Regulatory Environment (the No Action Alternative)

This section provides an overview of the major federal statutes and implementing regulations relating to paleontological and cultural resources to provide an understanding of the coordination and oversight that currently exists when impacts would occur. Many of the existing regulations apply only to federal actions, actions on federal lands, or actions occurring on lands held in trust by the federal government. OSMRE is a regulatory authority on Indian lands.

Section 3.13 describes generally where and under what conditions cultural and paleontological resources are expected to occur within the coal-bearing regions. These resources do not occur in all areas that are mined, and where they do occur it is also possible that the permit applicant would choose to avoid mining in the specific area to avoid the resources and associated regulatory requirements for coordination and mitigation.

Coal mining can affect cultural resources in a number of ways. Mining can impact archaeological artifacts and fossils (paleontological resources) due to the disturbance of the materials in which they lay. This disturbance can occur during earth moving activities associated with removal of the vegetation and roots prior to mining, or during removal of the materials (overburden) overlying the coal seam. Subsidence from underground mining can also impact cultural resources by disrupting the vertical position and alignment of artifacts; this can cause some of the information associated with the site to be lost. Subsidence is typically predictable and adverse effects can be planned for and mitigated in advance. Coal mining activities may also require the removal of historic properties during site preparation. Disturbance of these resources can destroy them or adversely affect their integrity to the extent where they are no longer significant on a national, state, or local level. As described below, statutes and regulations are in place to address these impacts during the permit process through identification of resources and coordination to develop and implement required protective measures. However, it is still possible that undiscovered resources may exist and be disturbed by mining activity.

4.3.5.1.1 Paleontological Resources

Existing federal laws that may affect the consideration and management of paleontological resources specifically during mining include SMCRA, NEPA, the Antiquities Act, and the Paleontological Resources Preservation Act. The discussion below focuses on the federal laws with most impact and applicability to surface mining effects on paleontological resources.

4.3.5.1.1.1 Surface Mining Control and Reclamation Act of 1977 (30 U.S.C. 1201 et seq.)

As discussed in Section 3.13, coal mining activities are known to coincide with areas known for fossil remains. Paleontological resources are not afforded specific protection under our existing regulations and OSMRE does not collect data on impacts to paleontological resources from coal mining. Given the intensive site disturbance associated with surface coal mining it is reasonable to assume that scientifically insignificant sites are impacted when they coincide with mining activity. Impacts to paleontological resources from coal mining would include physical damage, destruction, or other loss of fossils, or alteration or loss of contextual information. On the other hand, it is well documented that the excavation activities and subsidence associated with coal mining have resulted in the discovery of important paleontological sites. Mining exposes sediments that often have preserved organisms or casts within them (Parker and Balsley, 1989). Requirements to reclaim the site after mining can in fact conflict with the opportunity to leave the site open for further investigation. This was the case at the Steven C. Minkin Paleozoic Footprint Site in Alabama, formerly the Union Chapel Mine Site, at which more than 4000 fossil specimens have been collected (Geological Survey of Alabama State Oil and Gas Board, 2006).

Nothing in existing SMCRA regulations would preclude issuance of a permit to conduct mining that would impact paleontological resources, except where the SMCRA regulatory authority has designated the area as unsuitable for mining as discussed below or where a state with primacy has implemented additional regulations. Existing federal laws that may affect the consideration and management of paleontological resources during mining are summarized in the text below. Some states may have additional requirements, such as those in Montana, to consider impacts to paleontological resources on state lands.

The regulatory authority is authorized by section 522(e) of the SMCRA (30 U.S.C. § 1272(e)) to prohibit or limit surface coal mining operations on or near certain private, federal, and other public lands, subject to valid existing rights and except for those operations which existed on August 3, 1977. The implementing regulations require the regulatory authority, upon petition, to designate an area unsuitable for surface coal mining if mining there would affect fragile or historic lands in which the operations could result in significant damage to important historic, cultural, scientific, or esthetic values of natural systems (30 CFR 762.11). The definition of "fragile lands" per 30 CFR 762.5 specifically includes paleontological sites as an example. To date, OSMRE is unaware of any petition decisions that have designated areas as unsuitable for coal mining based partially or entirely on the need to protect paleontological resources.

Otherwise, neither SMCRA nor the current implementing regulations contain any requirement to identify, inventory, avoid, protect, or mitigate paleontological resources on federal or non-federal lands. On federal lands, the Antiquities Act applies, and, in practice, the regulatory authority sometimes addresses paleontological resources as part of the National Historic Preservation Act (NHPA) consultation where those resources are considered important as cultural markers in the discussion of traditional cultural value.

4.3.5.1.1.2 National Environmental Policy Act of 1969, as amended (42 U.S.C 4321, 4331-4335)

NEPA requires consideration of adverse effects to significant scientific, cultural or historical resources (40 CFR 1508.27(b)(8)). As such federal agencies are required to consider effects to scientifically or culturally important paleontological resources in evaluating actions to determine if the action would significantly impact the human environment. Paleontological resources are often included as a resource for consideration when federal agencies prepare NEPA documentation. Impacts to paleontological resources may differ between alternatives and in these instances these differences would be part of the information the decision maker has available for comparison of the reasonable alternatives and to determine the significance of impacts of the alternatives on the environment. However, NEPA applies only to federal actions (40 CFR 1500.1).

OSMRE would prepare NEPA documentation when the proposed mining activity would occur on federal or Indian lands, and for mining on all lands in the coal-producing states where OSMRE retains the role of regulatory authority (Tennessee and Washington). NEPA does not apply to state actions, including state permitting for mining on private lands. However individual states may have regulations and guidance that apply to actions affecting paleontological resources on state lands.[66]

4.3.5.1.1.3 Antiquities Act of 1906 as amended (54 U.S.C. §§ 320301 - 320303)

The Antiquities Act protects sensitive cultural resources on land owned or controlled by the federal government, and criminal penalties have been established for the removal, damage, or destruction of "any historic or prehistoric ruin or monument, or any object of antiquity that is situated on lands owned or

[66] Montana, for example, requires state agencies to include consideration of adverse effects on paleontological resources within state Environmental Impact Statements prepared for actions on state lands (MT Code § 22-3-433).

controlled by the federal Government, without the permission of the head of the federal agency having jurisdiction over the lands on which the object is situated" (18 U.S.C. § 1866). Though paleontological resources are not specifically mentioned, "objects of antiquity" has often been interpreted to include fossils and other paleontological resources (Harmon, et al., 2006). If the paleontological resource was considered to be an "object of antiquity", the removal of any objects would require a permit under the Antiquities Act (43 CFR 3.1).

4.3.5.1.1.4 Paleontological Resources Preservation Act of 2009 (16 U.S.C §§ 470aaa-470aaa-11)

In 2009, the Paleontological Resources Preservation Act (PRPA) was signed into law as part of the Omnibus Public Land Management Act. The requirements of the law have limited applicability to our responsibilities and authorities under SMCRA. The PRPA requires, in part, the Secretary of the Interior to manage and protect paleontological resources on lands "controlled or administered by the Secretary of the Interior, except Indian land" (16 U.S.C. §470aaa-1). The PRPA therefore applies to lands managed by the Bureau of Land Management, National Park Service, Bureau of Reclamation and the Fish and Wildlife Service. OSMRE is under the Department of the Interior but does not control or administer land.

The PRPA prohibits collection of paleontological resources from federal land without a permit, with some exceptions (16 U.S.C. § 470aaa-3), and prescribes civil penalties for acts such as damaging or removing paleontological resources located on federal lands (16 U.S.C. § 470aaa-5). However, the PRPA specifically clarifies that nothing in the law should be construed as invalidating, modifying, or imposing any additional restrictions or permitting requirements on any activities permitted at any time under the general mining laws, or laws providing for the management or regulation of these activities including SMCRA (16 U.S.C. § 470aaa-10). Under existing SMCRA regulations OSMRE (or a delegated state regulatory authority) would continue to be responsible for consulting with the federal land management agency with respect to any special requirements necessary to protect non-coal resources (such as paleontological resources) in the areas affected by surface coal mining and reclamation operations (30 CFR 740.4(c)(2)).

4.3.5.1.2 Cultural Resources

Existing federal laws that may affect the consideration and management of archaeological and historic resources specifically during mining include SMCRA; the NHPA; the Archaeological Resources Protection Act of 1979, as amended (16 U.S.C. § 470aa-470mm) (ARPA); the Antiquities Act, as amended (54 U.S.C. §§ 320301 – 320303); the Historic Sites Act of 1935, as amended (54 U.S.C. §§ 32101) (HSA); NEPA; the Historic and Archaeological Preservation Act of 1974, as amended (16 U.S.C. § 469; 54 U.S.C. §§ 312501-312508); the American Indian Religious Freedom Act of 1978, as amended (42 U.S.C. §§ 1996 and 1996a) (AIRFA); and the Native American Graves Protection and Repatriation Act of 1996 (25 U.S.C. §§ 3001-3013) (NAGPRA). The discussion below focuses on the federal laws with most impact and applicability to surface mining effects on cultural resources.

4.3.5.1.2.1 Surface Mining Control and Reclamation Act of 1977 (30 U.S.C. § 1201 et seq.)

As discussed in previous sections, most coal mining states have approved state programs for those states to regulate coal exploration and surface coal mining and reclamation operations on non-federal and non-Indian lands within their boundaries. The state, and not OSMRE, issues the mine permit where there is an applicable approved state regulatory program. State-issued permits under SMCRA are not federal undertakings for purposes of the NHPA.

While state issued permits are not federal undertakings afforded consideration under the NHPA, existing SMCRA-implementing regulations in 30 CFR 731.14(g)(17) require that state programs seeking federal approval include a process for consulting with state, federal and local agencies having responsibilities for historic, cultural, and archaeological resources. OSMRE's role in accordance with 30 CFR Part 732 is to ensure that implementation of approved state programs is no less effective than federal regulations.

Additionally, cultural resources are considered during review of amendments to state regulatory programs. The states are required to provide their proposed amendments to the State Historic Preservation Officer (SHPO) and Advisory Council on Historic Preservation (ACHP) for comment if those amendments would have an effect on historic properties (30 CFR 732.17(h)(4)).

Information regarding cultural resources is also required of permit applicants for specific proposed operations. For example, permit application packages for surface coal mining must contain descriptions of any cultural or historical sites listed on the National Register of Historic Places (NRHP) within the permit and adjacent areas of the proposed surface coal mining and reclamation operation (30 CFR 779.12(b)(1) and 783.12(b)). The regulatory authority may require the applicant to protect historic or archaeological properties on or eligible for listing on the NRHP through appropriate mitigation and treatment measures (30 CFR 780.31(b)).

Where OSMRE is the regulatory authority (e.g., on Indian lands, and in states without approved programs) or where federal lands are involved, the full federal agency requirements of the NHPA would apply in addition to the requirements of SMCRA. Where the proposed mining would occur on Indian lands the permit must also address compliance with federal laws aimed at protecting cultural resources on Indian lands in addition to compliance with the NHPA. On Indian lands, OSMRE is responsible for determining if the materials provided in the application are sufficient to determine possible adverse impacts on cultural resources (30 CFR 750.12(c)(3)(ii)(B)).

Gathering this information is important for the protection of these resources and also to determining whether existing prohibitions of 30 CFR 761.11(c) apply. With the exception of areas subject to valid existing rights (valid and existing rights are described at 30 CFR 761.16), surface coal mining is prohibited on any lands where mining will adversely affect any publicly owned park or any places included in the NRHP, unless jointly approved by the regulatory authority and the federal, state, or local agency with jurisdiction over the park or place (30 CFR 761.11(c)). Surface coal mining operations are also prohibited within 100 feet of cemeteries, although the regulations do allow for relocation of cemeteries to allow mining if authorization is granted by applicable state law or regulations (30 CFR 761.11(g)).

The information required in application packages can include information from the SHPO or Tribal Historic Preservation Officer (THPO) and from local archaeological, historical, and cultural preservation agencies. The regulatory authority can require the applicant to provide additional information including through further field investigation (30 CFR 779.12(b)).

Upon agreement of all parties that the operation can move forward despite adverse effects on listed or eligible historic or archaeological properties, the regulatory authority may require the applicant to protect historic or archaeological properties listed on or eligible for listing on the NRHP through appropriate mitigation and treatment measures (30 CFR 784.17(b)). Appropriate mitigation and treatment measures may be implemented after permit issuance, provided that the required measures are completed before the properties are affected by any mining operation (30 CFR 780.31(b) and 784.17(b)).

As discussed above, the regulatory authority can designate lands where mining would have an adverse effect on a publically owned park or any place included on the NRHP (not just eligible for it) as unsuitable for mining in coordination with the federal, state, or local agency with jurisdiction over the park or place (30 CFR 761.11(c)). However, permit applications that involve adverse impacts on these resources are not uncommon, and regulatory authorities routinely grant approval of these operations once consultation requirements are successfully completed.

Under all regulatory programs, consultations with the SHPO or THPO during the permit process help to avoid impacts to these resources where possible, and where not possible, identifies requirements for minimization and mitigation if the mining is allowed to move forward. Applicants sometimes choose to avoid the effect so that there is no need to pursue approval or to bear the cost or time delay associated with implementing mitigation required to resolve the effect.

4.3.5.1.2.2 National Historic Preservation Act of 1966 (54 U.S.C. § 300101 et seq.)

The NHPA requires federal agencies to take into account the effects of their undertakings on historic properties,[67] and to afford the ACHP a reasonable opportunity to comment 36 CFR 800.1(a). This procedure is commonly known as the "Section 106" process and the goal of consultation under this section is to identify historic properties potentially affected by the undertaking, assess its effects and seek ways to avoid, minimize or mitigate any adverse effects on historic properties (*Id*.). For specific properties, the federal agency taking the action determines eligibility of the resource in consultation with the appropriate SHPO or THPO (36 CFR 800.4).

The criteria for evaluation are broad so that a diversity of resources may meet eligibility requirements. Properties must display significance in American history, architecture, archaeology, engineering, and culture, while possessing integrity of location, design, setting, materials, workmanship, feeling and association (36 CFR 60.4). Additionally, in determining eligibility, NRHP considers the following criteria (36 CFR 60.4):

- **Criterion A:** Properties associated with the events that have made a significant contribution to the broad patterns of American history; or
- **Criterion B:** Properties associated with the lives of persons significant in our past; or

---

[67] Historic properties as defined under the NHPA are any prehistoric or historic district, site, building, structure, or object included in or eligible for inclusion on the NRHP (36 CFR 800.16(l)). Historic properties under the NHPA may also include traditional cultural properties listed on the NRHP. This term "historic properties" corresponds to the phrase used in SMCRA and the implementing regulations "historic or archaeological resources listed or eligible for listing" (30 CFR 779.12b(1)).

- **Criterion C:** Properties that embody the distinctive characteristic of a type, period, or method of construction, or that represent the work of a master, or that possess high artistic value, or that represent a significant or distinguishable entity whose components may lack individual distinction; or

- **Criterion D:** Properties that have yielded or may likely yield information important in prehistory or history.

The responsibilities of the SHPO or THPO under the NHPA extend to undertakings funded in whole or in part under the direct or indirect jurisdiction of a federal agency, including those carried out by or on behalf of a federal agency; those carried out with federal financial assistance; and those requiring a federal permit, license or approval (36 CFR 800.16(y)). The ACHP recognizes that federal agency influence on activities that take place on non-federal lands is generally limited to conditioning the assistance, permit, or license with stipulations setting what the recipient will do, not necessarily how the applicant will do it (ACHP, 2006).

The NHPA requires federal agencies to consult with federally recognized Indian tribes that attach religious or cultural significance to historic properties (54 U.S.C. § 302706(b)). The NHPA requires tribal consultation not only for tribal lands but also for ancestral homelands of an Indian tribe or tribes (36 CFR 800.2(c)(2)). Properties with traditional cultural significance may be eligible for inclusion in the NRHP. The National Register Bulletin 38 (Parker and King, 1992) justifies their inclusion by defining a traditional cultural property (TCP) as one that is "eligible for inclusion in the National Register because of its association with cultural practices or beliefs of a living community that (a) are rooted in that community's history, and (b) are important in maintaining the continuing cultural identity of the community." Such properties may be a simple, unmodified location, a mountain peak, a rural community, an urban neighborhood, or any other place that holds important meaning for a community. TCPs may be encountered across the country. States with extant Native American lands and populations might be expected to contain more TCPs than other parts of the country. The extremely variable nature of TCPs, and their often secret nature and poor documentation, makes it impracticable to learn or describe the TCP resources of each state here in this FEIS.

Methodologies for cultural resource evaluations and treatment of artifacts retrieved from archaeological sites are contained in the implementing regulations for the NHPA at 36 CFR Part 63 (Determination of Eligibility for Inclusion in the National Register) and 36 CFR Part 79 (Curation of Federally-Owned and Federally Administered Archaeological Collections). Artifacts recovered from private lands during archaeological surveys and excavation during the course of Section 106 review are usually the property of the landowner, unless state or local law mandates otherwise. Human remains are generally covered under specific laws. On federal land, human remains are addressed under NAGPRA (43 CFR Part 10); on non-federal lands, state laws would apply.

The NHPA requires resolution of adverse effects only for impacts to resources listed or eligible for listing on the NRHP, as discussed in the implementing regulations at 36 CFR 800.6. Despite data from cultural resources inventories, sites and resources remain unknown, and it is therefore possible that inadvertent impacts could occur to previously unidentified sites during mining. The NHPA recognizes this possibility and includes procedures to address post discovery situations as they arise (36 CFR 800.13).

4.3.5.1.2.3 Archaeological Resources Protection Act (16 U.S.C. § 470aa-470mm)

The ARPA and its implementing regulations at 43 CFR Part 7, address legitimate archaeological investigation on public lands and provide for enforcement actions against vandals and looters of these resources. Section 9 of ARPA specifically prohibits the release of information concerning the nature and location of archaeological sites excavated or removed under an ARPA permit unless the federal land manager determines that releasing the information furthers the purposes of ARPA and will not create a risk of harm to the resources (16 U.S.C. § 470hh). The purposes of ARPA as set out at 16 U.S.C. § 470aa are: "to secure, for the present and future benefit of the American people, the protection of archaeological resources and sites which are on public lands and Indian lands, and to foster increased cooperation and exchange of information between governmental authorities, the professional archaeological community, and private individuals. . ." Therefore, information from archaeological sites on private lands or non-federal public lands is protected under ARPA.

4.3.5.2 Action Alternatives and Potential Effects on Archaeological, Paleontological and Cultural Resources

Additional impacts to cultural and paleontological resources from the rule elements would only occur if the element increases the area of ground disturbance related to the mining operation or shifts the operation from one area to another area of differing probability for containing these resources. Therefore, the majority of the discussion of impacts of the rule elements on topography, geology and soils also applies to the discussion of impacts on cultural and paleontological resources. To the extent that any particular rule element reduces the extent of ground disturbance associated with mining, it would also reduce the disturbance of cultural resources located within that ground. Therefore cultural resources may benefit from some or all of the rule elements.

4.3.5.2.1 Protection of the Hydrologic Balance

4.3.5.2.1.1 Baseline Data Collection and Analysis

Baseline data collection has the potential to affect cultural and paleontological resources under all of the Alternatives under consideration; collection of this data is required under the No Action Alternative and would be expanded under most (all but Alternative 9) of the Action Alternatives. However, the likelihood of effects of this activity on cultural and paleontological resources is reduced due to the fact that direct impacts would be limited to the area of disturbance associated with the sampling, and in order for a direct impact to occur the sampling location would have to coincide with the location of the resources themselves. The regulatory authority would review these proposed activities during the permit process. The permit application package must identify cultural resources, and the location of the baseline data sampling activity could be adjusted to avoid impacts in most instances.

4.3.5.2.1.2 Monitoring During Mining and Reclamation

It is unlikely that activities related to this element would affect paleontological or cultural resources. Hydrologic monitoring itself requires little or no ground disturbance other than the installation of monitoring wells as discussed above, and avoidance of important resources should be possible in almost all circumstances.

Groundwater data is required under existing regulations of the No Action Alternative; several of the Action Alternatives (all but Alternative 9) would increase the list of analytes required and the frequency of data collection. Increasing the list of analytes and the frequency of collection would not increase the number of wells installed. However, the proposed revisions would also further clarify the findings that must be made based on this data, and as a result the number of wells installed on any particular mine site may increase under these Action Alternatives. The area of disturbance associated with a monitoring well is generally small-consisting of the roadway used to haul equipment to the well site, the area used during drilling, and the final installed well.

Increased monitoring requirements would also potentially increase impacts to paleontological and cultural resources as a result of changes to the mining operation that the improved data may show as necessary. The remedy to the problem may require a change to the ongoing mining operation, such as the rerouting of a drainage system or the construction of a new treatment pond, which would increase the area of disturbance. However, as with existing regulations, the regulatory authority would review these changes to the mining plan under existing SMCRA regulations that require identification of impacts to cultural resources and allow the regulatory authority to require mitigation.

4.3.5.2.1.3 Definition of Material Damage to the Hydrologic Balance

As with the collection of baseline data and subsequent monitoring, the result of the definition of material damage to the hydrologic balance could induce indirect effects on the area of disturbance. Alternatives 2, 3, 4, and 8 (Preferred) would therefore have a slightly increased risk of disturbance of these resources in comparison to Alternatives 1 (No Action), 5, 6, 7 and 9. However the requirements of the existing regulations pertaining to consideration of impacts at the permitting stage would continue to apply regardless; the regulatory authority would review these changes to the mining plan under existing SMCRA regulations, and would require mitigation identified through consultation as required.

4.3.5.2.1.4 Evaluation Threshold

Evaluation thresholds are impact standards set lower than those established for material damage to the hydrologic balance and are designed to act as a warning system to prevent material damage to the hydrologic balance outside the permit area. Under the No Action Alternative, no evaluation thresholds exist and also are not proposed in Alternatives 5, 6, and 9. The establishment of evaluation thresholds, as proposed in Alternatives 2, 3, 4, 8 (Preferred) and, in certain circumstances, Alternative 7, could trigger a redesign in the mining operation. As described above for the other components of the elements related to protection of the hydrologic balance, the additional requirement of an evaluation threshold may introduce additional potential for ground disturbance and additional risk of impacts to cultural and paleontological resources.

4.3.5.2.2 Activities in Or Near Streams

4.3.5.2.2.1 Stream Definitions

Modifying the definition of streams may affect paleontological or cultural resources. Our existing regulations (the No Action Alternative) classify all watersheds one square mile or larger in size as intermittent streams. Alternatives 3, 5, 6 and 9 would make no change to this definition. However, Alternatives 2, 4, 7 (when warranted by the operation) and 8 (Preferred) would replace the watershed component of the definition with other determining characteristics. To the extent that this change would result in some streams (mostly in the arid and semiarid regions of the West) now protected as intermittent streams being reclassified as ephemeral streams, which lack the protections afforded to perennial and intermittent streams, there could be a direct effect on aquatic resources and the streamside area associated with the stream through increased disturbance (as discussed in the other sections of this chapter). If those newly disturbed areas also contained paleontological or cultural resources this redefinition could result in an effect.

4.3.5.2.2.2 Mining through Streams

The predominant interpretation of the existing regulations (No Action Alternative) allows diversion and mining through intermittent and perennial streams when the regulatory authority makes a finding that diversion of the stream would not adversely affect water quantity, water quality, and related environmental resources of the stream (30 CFR 816.43(b) and 817.43(b)). Alternatives 2 and 7 (when enhanced permitting conditions apply) explicitly prohibit all mining activities in or within 100 feet of perennial streams but, with certain additional requirements as described elsewhere, allow mining through intermittent and ephemeral streams. However each of the Action Alternatives includes additional requirements related to restoration of mined through streams, and these additional requirements may deter some applicants from proposing these activities and therefore reduce the amount of disturbance of resources through avoidance.

Impacts to paleontological and cultural resources would occur during the excavation of the streambed for the mining through activity, and due to the disturbance associated with creating a diversion channel to receive the water that would otherwise have flowed through the mined through stream. Mining through streams may have a higher risk of impact on cultural resources in comparison to mining in upland areas. Streams and stream side areas are attractive for many human uses and cultural practices; these areas may have a higher probability of containing artifacts than other areas that are farther from water. However, this probability must be evaluated carefully on a case-by-case basis because erosion and human manipulation may have changed the location and course of the water body substantially over time. As with the No Action Alternative, if proposed impacts to the stream would affect NRHP eligible resources, consultation requirements under NHPA and SMCRA would apply.

4.3.5.2.2.3 Activities in or Near Streams, Including Placement of Excess Spoil and Coal Refuse

Under the No Action Alternative, mining activities within 100 feet of intermittent or perennial streams are prohibited unless the regulatory authority specifically authorizes activities closer to or through the stream. Such authorization requires a finding that the mining activities would not cause or contribute to the violation of applicable state or federal water quality standards and would not adversely affect the water quantity or quality or other environmental resources of the stream.

The Action Alternatives would increase the stringency of the requirements governing mining activities near streams as well as the placement of excess spoil and coal refuse at these locations. All Action Alternatives would require minimization of excess spoil creation. The proposed new requirements would potentially indirectly benefit paleontological and cultural resources because the requirements to minimize excess spoil creation would result in less area needed to accept the excess spoil, thereby potentially reducing the likelihood of impacted areas containing cultural or paleontological resources. The benefits may be minor; not all areas contain these resources, and existing regulations already contain requirements for identification and protection as described previously.

These impacts would continue under all of the Action Alternatives; all of the Action Alternatives allow mining through streams to some extent although Alternatives 2 and 4 (and 7 when special conditions exist) would prohibit mining through perennial streams. However each of the Action Alternatives (excluding Alternative 9) includes additional requirements related to restoration of mined through streams, and these additional requirements may deter some applicants from proposing these activities and therefore reduce the amount of disturbance of resources through avoidance.

4.3.5.2.3 Approximate Original Contour (AOC) Variances and Surface Configuration

SMCRA requires that the permittee backfill and grade the mined area to its AOC, which means a surface configuration that closely resembles the premining surface configuration and that blends into and complements the drainage pattern of the surrounding terrain. However, the No Action Alternative contains no numerical standards for use in determining when this requirement has been achieved. SMCRA and the existing regulations (the No Action Alternative) provide for a number of exceptions to the requirement to restore mined land to AOC. Those exceptions include operations with thin or thick overburden, certain remining operations, mountaintop removal mining operations, and steep-slope mining operations.

While the Action Alternatives (excluding Alternative 9) propose changes to these regulations this topic has little relevance to paleontological or cultural resources since it pertains to the return of the land to specified conditions after the mining has occurred; any disturbance of paleontological or cultural resources would have occurred before this point in the operation (e.g., during site preparation and overburden removal).

4.3.5.2.4 Postmining Land Use and Enhancement

4.3.5.2.4.1 Revegetation, Soil Management, and Reforestation

This rule element pertains to the handling of soils during overburden removal for the purposes of salvaging their potential as a growing medium during reclamation, and requirements for revegetating after the mining activity. The No Action Alternative emphasizes use of native species in revegetation, although introduced species are permitted under certain conditions. Salvage, storage, and redistribution of topsoil (the A and E soil horizons) are required for all operations with exceptions for prime farmland.

Additional requirements under the Action Alternatives (excluding Alternative 9) for salvage of organic materials and soils (as described in Chapter 2) may have a Minor Beneficial impact on paleontological and cultural resources by increasing the amount of handling of the soil and therefore the potential for discovery of unearthed artifacts that were not known to be in the area. The Action Alternatives (excluding Alternative 9) would pose no additional negative risks because these specific proposed requirements would not increase the area of disturbance. Temporary storage of these materials typically occurs in the areas already disturbed, through phasing of the mining and reclamation activities.

4.3.5.2.4.2 Fish and Wildlife Protection and Enhancement

The No Action Alternative prohibits mining activity likely to jeopardize endangered or threatened species. Likewise, current regulations require the enhancement of fish and wildlife resources where practicable, and contain specific provisions applicable to power lines, haul and access roads, fences, and toxic industrial ponds. Existing regulations also require avoidance of disturbances to, restoration, or replacement of wetlands, streamside vegetation, and other habitats of unusually high value for fish and wildlife.

The Action Alternatives (excluding Alternative 9) contain elements designed to further protect and enhance fish, wildlife, and related environmental resources. The new requirements include establishment or restoration of a minimum 100-foot (Alternatives 2, 5, 6, 7, and 8 (Preferred)) or 300-foot (Alternatives 3 and 4) streamside vegetative corridor comprised of native species along intermittent, perennial, and (sometimes) ephemeral streams. To the extent that this element reduces the overall spatial extent of mining it could also in turn reduce the potential for disturbance of paleontological or cultural resources if the avoided areas contain these resources.

4.3.5.3 Summary of Effects

The discussion in this section is brief because none of the Action Alternatives include any proposed changes within the regulations that directly address these resources. Any effects would be indirect and would occur only as a result of effects on other resources, specifically to geology and soils, and then only if paleontological and cultural resources are present in the disturbed area.

4.4 Environmental justice

This section of Chapter 4 identifies communities that meet defined environmental justice criteria and explains the potential effects of the Action Alternatives on these communities.

This section:

- Identifies sensitive minority, low-income, and American Indian populations; and
- Discusses the potential impacts of the Action Alternatives on these populations, including impacts on socioeconomic resources, public health and safety, biological resources, water resources, air quality, topography, land use, and recreation.

Environmental justice requires the balanced treatment of all individuals with respect to the development, implementation, and enforcement of environmental regulations, laws, and policies. Likewise, it calls for the meaningful inclusion and representation of all parties in the decision-making process of new environmental statutes (U.S. EPA, 1998). In accordance with Executive Order 12898, the purpose of considering environmental justice in the context of implementing a new regulation is to ensure that adverse human health and environmental effects are not disproportionately experienced by minority and low-income populations. This section addresses potential environmental justice effects emanating from the Action Alternatives as compared to the No Action Alternative.

The intent of an environmental justice evaluation under Executive Order 12898, “Federal Actions to Address Environmental Justice in Minority and Low Income Populations” (1994), is to identify communities and groups that meet environmental justice criteria, and suggest strategies to reduce potential adverse impacts of projects on affected groups. The purpose of Executive Order 12898 is to identify and address the disproportionate placement of adverse environmental, economic, social, or health impacts from federal actions and policies on minority and/or low-income communities. This order requires lead agencies to evaluate impacts on minority or low-income populations during preparation of environmental and socioeconomic analyses of projects or programs that are proposed, funded, or licensed by federal agencies.

4.4.1 Identification of Sensitive Minority, Low-Income, and American Indian Populations

According to the Council on Environmental Quality (CEQ) and EPA guidelines established to assist federal and state agencies, a minority population is present in a project area if (1) the minority population of the affected area exceeds 50 percent, or (2) the minority-population percentage of the affected area is meaningfully greater[68] than the minority-population percentage in the general population or other appropriate unit of geographic analysis. By the same rule, a low-income population exists if the project area consists of 50 percent or more people living below the poverty threshold, as defined by the U.S. Census Bureau, or is meaningfully greater[69] than the poverty percentage of the general population or other appropriate unit of geographic analysis.

Per Executive Order 12898, minorities are defined as individuals of the following population groups: American Indian or Alaskan Native; Asian or Pacific Islander; Black, not of Hispanic origin; or Hispanic. This analysis also considered the minority groups “Two or More Races” and “Other.”

The CEQ guidance indicates that when agencies determine whether environmental effects are “disproportionately high and adverse,” they are to consider whether there is or would be an impact on the natural or physical environment (as defined by NEPA) that would adversely affect a minority population or low-income population. None of the published guidelines define the term “disproportionately high and adverse,” but CEQ includes a non-quantitative definition stating that an effect is disproportionate if it appreciably exceeds the risk or rate to the general population (CEQ, 1997).

The affected area for this analysis is large and spans a variety of demographic conditions. In total, the affected area contains seven coal regions encompassing 286 counties in 24 states. The analysis was conducted at a county level to determine if any of the 286 counties contain populations that meet environmental justice criteria. Indian Tribes are considered as a distinct category in the minority population environmental justice analysis (see Section 4.4.3).

---

[68] The term “meaningfully greater” is not quantitatively defined and is therefore interpreted independently for each federal analysis that considers environmental justice populations. A survey of eight recent analyses, including several environmental impact statements for coal projects, revealed thresholds for “meaningfully greater” populations ranging from 1.2 to three times larger than the general geographic area. This analysis uses a threshold within this range to identify meaningful environmental justice populations. In the context of this study, a minority population in a study area was considered meaningfully greater if it was greater than or equal to two times (double) the minority population percentage at the state level.

[69] In the context of this study, a low-income population in a study area was considered meaningfully greater if it was greater than or equal to the low-income population percentage at the state level.

Table 4.4-1 presents those counties that have a minority population that meets the environmental justice criteria. A county was included in Table 4.4-1 if (1) the minority population was greater than 50 percent of the county population, or if (2) the minority population in the county made up a percent of the population that was at least double the percent of the minority population at the statewide level.

Table 4.4-1a. Black or African American Minority Populations meeting the Environmental Justice Criteria within Coal-Producing Counties

County	State	Region	Percent Population Minority (County)	Percent Population Minority (State)	Ratio of County to State Minority Population
McDowell	West Virginia	Appalachian Basin	9.5%	3.4%	2.79

*County appears twice in the table set because they meet the criteria for more than one minority group.

American Indians have a greater representation within several coal region counties than they do within the rest of the state in which those counties are located. Most notably, Big Horn and Rosebud counties in the Northern Rocky Mountains and Great Plains region, Navajo, McKinley, and La Plata counties in the Colorado Plateau region, and Kemper County in the Gulf Coast region all have American Indian populations that are at least five times greater, as a percent of the population, than American Indian populations for the states in which the counties are located.

Five counties appear in Table 4.4-1 for at least two different minorities. These are Christian County in Kentucky (Black/African-American and American Indian), De Kalb County in Alabama (American Indian, Hispanic Origin, and Other), Kemper County in Mississippi (Black/African-American and

American Indian), Las Animas County in Colorado (American Indian and Hispanic Origin), and Sebastian County in Arkansas (American Indian, Asian, and Other).[70]

Table 4.4-2 presents those counties that have a low-income population that meets the environmental justice criteria. A county was included in Table 4.4-2 if the low-income population in the county was greater than or equal to the percent of the low-income population at the statewide level. As shown, of the 286 counties in the study area, 185 counties have a higher percent of the population living below the poverty line than the average of the state in which the county occurs. Unlike the minority populations discussed above, the low-income populations of concern are geographically concentrated: of the 185 counties, 112 are located in the Appalachian Basin region (61 percent), while 31 are located in Illinois Basin (11 percent), 14 in Gulf Coast, 10 each in Colorado Plateau and Northern Rocky Mountains and Great Plains regions (5 percent each), seven in Western Interior (4 percent), and one in the Northwest region (1 percent). Within the 112 counties in Appalachia with poverty rates that are higher than state averages within the study area, 28 counties are in Kentucky, 22 counties are in West Virginia, 21 counties are in Pennsylvania, 18 counties are in Ohio, and 23 counties are in other states in the region (Alabama, Tennessee, Virginia, and Maryland).

Table 4.4-2a. Low-Income Populations in Coal-Producing Counties in the Appalachian Basin

County	State	Percent Population Below Poverty Line (County)	Percent Population Below Poverty Line (State)

Breathitt	Kentucky	30.0%	18.1%
Clay	Kentucky	36.5%	18.1%
Elliott	Kentucky	31.9%	18.1%

[70] It should be noted that "Hispanic Origin" is classified as an ethnicity and not a race. On the U.S. Census form, an individual may self-identify as both a particular race and of Hispanic origin. As such, duplicate representation of counties in the table may be due, in part, to multiple answers supplied by a single individual.

Source: U.S. Census Bureau, 2013. Census 2010.

Of the 286 counties in the study area, there are 190 counties that have populations that meet the previously specified low income and/or the minority population environmental justice thresholds. Of these 190 counties, 60 percent of them are in the Appalachian Basin. Of those counties in the Appalachian Basin, four have been identified as minority communities, 103 as low income communities, and nine as both low income and minority environmental justice communities. The minority communities identified as potentially affected environmental justice populations in this region are as follows: Black or African American; American Indian and Alaskan Native; Asian, Native Hawaiian or Other Pacific Islander; Hispanic Origin; and Other.

There were six counties in the Colorado Plateau identified as potentially affected low income populations and four counties identified as both low income and minority environmental justice communities. Minority populations included American Indian and Alaskan Native. In the Gulf Coast region, three counties had populations that met the criteria for environmental justice low income and minority populations, 11 counties were identified as only low income communities, and one county was identified as a minority community (Black or African American, American Indian and Alaskan Native, and Hispanic Origin).

In the Illinois Basin, 28 counties met the criteria for low income populations and three counties met environmental justice thresholds for both low-income and minority populations (Black or African American; and American Indian and Alaskan Native). In the Northern Rocky Mountains and Great Plains region, three counties were identified as minority communities, six as low income communities, and four as both low income and minority environmental justice communities. The minority communities identified as potentially affected environmental justice populations in this region are as follows: American Indian and Alaskan Native; Hispanic Origin; and Other. In the Northwest, one county was identified as a low income environmental justice community. In the Western Interior, one county was identified as both low income community and minority population. Six counties met environmental justice low income population thresholds only and two counties met minority population thresholds only. Three counties identified for minority populations met environmental justice criteria for American Indian and Alaskan Native minority populations. One of the counties also has minority populations of Asian, Native Hawaiian or Other Pacific Islander and Other that meet environmental justice criteria.

Mining occurs in close proximity to or on a number of tribal reservations. The Northern Cheyenne Indian Reservation is situated in both Big Horn and Rosebud Counties in Montana where five active surface mines exist. In addition, the Crow Indian Reservation covers nearly 65 percent of Big Horn County. San Juan County overlaps both the Navajo Nation Reservation and the Ute Mountain Reservation where one active surface mine and one active underground mine exist. The Zuni Reservation is located primarily in McKinley County where two active surface mines exist. McKinley County also overlaps with the Navajo Nation Reservation. Navajo County in Arizona is comprised of the Navajo Nation Reservation, the Fort Apache Reservation, and the Hopi Reservation where one active surface mine exists.

Of particular note are mines located on (not just near) tribal land. For example, the Navajo Mine and the Kayenta Mine are operated on the Navajo Nation lands and produce about 15 million tons of coal annually (U.S. EIA, 2012c). An additional coal mine, the Absaloka Mine, is located on the Crow Reservation in Montana.

4.4.2 Discussion of Potential Impacts to Minority, Low-Income, and American Indian Populations

As stated previously, the purpose of Executive Order 12898 is to identify and address the disproportionate placement of adverse environmental, economic, social, or health impacts from federal actions and policies on minority and/or low-income communities. Impacts disproportionately experienced by minority and low-income populations may be environmental, economic, social, or human health related. This analysis examines any negative or positive impacts on these parameters resulting from changes to coal mining under the Action Alternatives as compared to the No Action Alternative. In particular, the analysis considers the manner in which impacts of the Action Alternatives may interact with existing cultural, social, occupational, historical, or economic factors defining minority, low-income, and Indian Tribe groups such that the adverse effects are amplified and experienced disproportionately by these environmental justice populations.

4.4.2.1 Socioeconomic Conditions

Overall, coal production is expected to decrease under the implementation of the Action Alternatives (excluding Alternative 9) as compared to the No Action Alternative.[71] The negative economic impacts resulting from this reduced coal production may be disproportionately experienced by the minority, low-income, and American Indian environmental justice populations previously identified. However, the adverse economic effects are not expected to be uniform across coal regions. Section 4.3.1 provides a sense of the socioeconomic impacts of the Action Alternatives by region. Economic impacts would be expected to be especially notable in places in which the identified environmental justice population is particularly dependent on the revenue streams associated with coal production. There may also be more direct effects where the coal mine is owned and operated by the minority population. For instance, the Navajo Transitional Energy Company (NTEC), a Navajo Company, is the owner and operator of the Navajo surface coal mine in San Juan County New Mexico.

- Under Alternatives 2, 3, 6, 7 and 8 (Preferred): the Appalachian Basin, Illinois Basin, and Northern Rocky Mountains and Great Plains are expected to incur adverse socioeconomic effects; Negligible effects are expected for all other regions. In the Appalachian Basin, 103 counties have populations that meet the criteria for low-income environmental justice communities and four for minority populations, with nine counties falling into both categories. In the Illinois Basin, four counties have an American Indian and Alaskan Native environmental justice population. In seven counties in the Northern Rocky Mountains and Great Plains region there are three environmental justice minority populations: Asian, Native Hawaiian, Pacific Islander, or Other; Hispanic Origin; and Other. Negligible effects on socioeconomic conditions are expected for all other regions.

- Under Alternative 4: the Appalachian Basin and Illinois Basin are expected to incur Moderate and Minor Adverse socioeconomic effects. In the Appalachian Basin, 103 counties have populations that meet the criteria for low-income environmental justice communities and four for minority populations, with nine counties falling into both categories. In the Illinois Basin, four counties have an American Indian and Alaskan Native environmental justice population. The Northern Rocky Mountains and Great Plains region is expected to experience Minor Beneficial socioeconomic effects. Negligible effects on socioeconomic conditions are expected for all other regions.

- Under Alternative 5: the Appalachian Basin is expected to incur Moderate Adverse Socioeconomic effects. In the Appalachian Basin, 103 counties have populations that meet the criteria for low-income environmental justice communities, four meet the criteria for minority populations, and nine counties fall into both categories. Minor Adverse socioeconomic effects are expected in the Northern Rocky Mountains and Great Plains region, and there are three

[71] Coal production is unchanged under Alternative 9 when compared to the No Action Alternative.

environmental justice minority populations in that region (as mentioned previously). Negligible effects on socioeconomic conditions are expected for all other regions.

- Under Alternative 9: Negligible effects on socioeconomic conditions are expected for all regions.

4.4.2.2 Public Health and Safety

Across all regions and Alternatives, health impacts are expected to range from Negligible to Major Beneficial; no adverse health impacts are expected. Beneficial impacts to health, such as reduced exposure to pollutants in drinking water would generate an overall beneficial effect on health and safety.

4.4.2.3 Biological Resources, Water Resources, and Air Quality

Under the Action Alternatives, environmental effects, including water quality and forest land restoration are generally expected to be positive (other than under Alternative 9). Depending on the specific environmental resource and the Alternative, the beneficial effects are anticipated to range from minor to major. Under all of the Action Alternatives and across all regions, effects on air quality, greenhouse gas emissions, and climate change are expected to be Beneficial or Negligible. Therefore, effects on identified environmental justice communities are expected to be beneficial or negligible with respect to biological resources, water resources, and air quality.

4.4.2.4 Topography and Land Use

Topography, geology, and soils are expected to experience Beneficial or Negligible impacts under the Action Alternatives. Similar impacts are expected for land use, utilities, infrastructure, visual resources, and noise. Across all Action Alternatives and regions, no adverse impacts are expected for these resources. Therefore, effects on identified environmental justice communities are expected to be Beneficial or Negligible with respect to topography and land use.

4.4.2.5 Recreation

Recreational resources are also predicted to experience beneficial impacts as a result of the Action Alternatives (other than Alternative 9). Participation in hunting, fishing, and wildlife viewing is high among American Indians (U.S. FWS, 2006a), suggesting that positive impacts to such recreational opportunities may be amplified within these communities. Additionally, frequent hunting is closely tied to food consumption in rural Appalachia (Wenrich et al., 2010). To the extent that these communities use areas that benefit from the Action Alternatives, these communities may experience greater positive impacts on wildlife and hunting.

4.4.3 Discussion of Other Effects Specific to Native American Tribes

The U.S. Census identifies 20 “American Indian Areas” and six “Alaska Native Village Statistical Areas” (ANVSA) within the coal-producing regions studied in this FEIS. These include reservations, off-reservation trust lands, and statistical areas that include populations of Native Americans and Alaska Natives. These areas, mapped in Section 3.14, overlap potentially minable coal within coal-producing counties across the U.S., and coal mining often occurs on or in close proximity to a number of reservations.

As mentioned previously and discussed in Section 3.14, this analysis gives particular emphasis to the Navajo, Hopi, Northern Cheyenne, and Crow Tribes, the four tribes listed in the Surface Mining Control and Regulation Act (SMCRA) (30 U.S.C. § 1300(i)). The Navajo Nation Reservation occupies northeastern Arizona, southeastern Utah, and northwestern New Mexico. The Hopi Reservation lies entirely within the Arizona portion of the Navajo Reservation. The Northern Cheyenne Reservation and Off-Reservation Trust Land and Crow Reservation and Off-Reservation Trust Land lie adjacent to one another in southeastern Montana.

In general, the potentially affected Native American tribes are less affluent than the broader national population. Median household income is less than the national statistic in 18 of the 20 examined "American Indian Areas." Employment by industry for the 20 American Indian areas and six ANVSAs is presented in Table 3.14-20 in Section 3.14. While specific data regarding employment in the coal mining industry is not available for these populations, the Agriculture, Forestry, Fishing, and Hunting, and Mining (including but not limited to coal mining) industries account for 18 percent of total employment in the Uintah and Ouray Reservation and Off-Reservation Trust Land. In the Navajo Nation and Northern Cheyenne Reservations and Off-Reservation Trust Lands, Agriculture, Forestry, Fishing, and Hunting, and Mining account for nearly four percent of total employment. In the Crow and Hopi Reservations and Off-Reservation Trust Lands, these industries make up 14.4 percent and 4.6 percent of total employment. To the extent that the proportion of American Indians working in the coal industry is greater than that of the statewide population, the projected reduction in coal production, under all the Action Alternatives (excluding Alternative 9), would have a disproportionate burden on these environmental justice communities.

There are four primary federal laws applicable to protection of all cultural resources on federal lands: the Antiquities Act of 1906, the National Historic Preservation Act (NHPA), the National Environmental Policy Act (NEPA), and the Paleontological Resources Preservation Act. Nothing in the Action Alternatives alters the protections offered by these public laws or their implementing rules and regulations. Together these four laws and their accompanying rules provide a strong basis for protection for any cultural properties that may be encountered when coal mining occurs on federal lands.

In addition, for all coal mining permit applications (including those on private lands), SMCRA regulations under 30 CFR 761.11(g) require permit applications, reclamation plans, and operations plans to prohibit mining within 100 feet of any cemetery. The identification of important historic and archaeological resources are covered under 30 CFR 779.12(b)(2) and 783.12(b)(2). Lastly, under 30 CFR sections 780.31 (surface mining) and 784.17 (underground mining), for any publicly owned parks or any places listed on the National Register of Historic Places that may be adversely affected by the proposed operation, each reclamation and operation plan must describe the measures to be used to prevent adverse impacts.

Nothing in the Alternatives proposes to alter or change regulations that are protective of archaeological and paleontological resources in any way. Any effects from the Alternatives on cultural, archaeological, or paleontological properties would be indirect and Negligible (see Section 4.3.5) and would therefore have minimal potential for additional impacts to any sensitive environmental justice population.

4.5 Cumulative Impacts

This section of Chapter 4 presents projected cumulative impacts for the Action Alternatives. This section:

- Describes the background and scope of cumulative impact analyses;
- Identifies and describes past, present, and reasonably foreseeable future actions that could interact with the Alternatives; and
- Presents an assessment of the cumulative impacts by resource and Alternative.

4.5.1 Background and Scope

NEPA requires all environmental impact statements for proposed federal actions to include a cumulative effects analysis that examines the impact of the actions in conjunction with other factors that affect the physical, biological, and socioeconomic resource components of the affected environment (40 CFR 1508.25). NEPA defines a cumulative impact as an "impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency or person undertakes such other actions" (40 CFR 1508.7). Guidelines for evaluating cumulative effects, prepared by the Council on Environmental Quality (CEQ), emphasize the growing evidence that "the most devastating environmental effects may result not from the direct effect of a particular action, but from the combination of individually minor effects of multiple actions over time" (CEQ, 1997).

The previous sections of Chapter 4 have examined direct and indirect impacts of the Alternatives. This chapter assesses cumulative impacts by considering the direct/indirect impact of the Alternatives in combination with past, present, and reasonably foreseeable future actions as of 2014. Specifically, cumulative impacts are assessed with respect to each of the major resource categories, including:

- Water resources;
- Biological resources;
- Geology, soils, and topography;
- Air quality, greenhouse gas emissions, and climate change;
- Socioeconomic conditions;
- Land use, utilities, infrastructure, visual resources, and noise;
- Public health and safety;
- Archaeological, paleontological, and cultural resources; and
- Recreation.

As described in Chapter 4.0 of this EIS, coal resources in the U.S. are widely distributed throughout the country. However, not all coal resources are accessible with current technologies. Further, some potentially mineable coal resources are unlikely to be mined in the near term because of economic conditions. To establish a reasonable boundary for the geographic areas likely to be affected by this rule, the geographic scope was defined as outlined below. In general, the geographic scope identified is likely to be over-inclusive; it may overestimate the areal extent of mining, unless otherwise noted.

Spatial data compiled by the U.S. Geological Survey (USGS) Eastern Energy Resources Center on potentially minable coal fields defined the initial extent of the study area. Coal fields were identified as potentially minable if they contained coal of sufficient quality and energy content to justify extraction, based on existing data (USGS, 2001b).

From the practicably minable coal fields data, areas considered likely to produce coal within the timeframe for this analysis include areas within counties that:

- Reported coal production between 2007 and 2012 in Energy Information Administration (EIA) Annual Coal Reports;
- Contain pending but administratively complete Surface Mining Control and Reclamation Act (SMCRA) permits in the Office of Surface Mining Reclamation and Enforcement (OSMRE) Applicant/Violator System (AVS) as of September 2011;
- The Mine Safety and Health Administration (MSHA) reports as containing active coal mines as of April 2013 (MSHA, 2013b); or
- State-level mining assessments, geographic data, or tabular data report as containing active coal mining activity as of August 2012. State-level information contributed additional counties in Colorado (Colorado Division of Reclamation Mining and Safety, 2010), Illinois (Illinois State Geological Survey, 2011), Kentucky (Kentucky Department of Natural Resources, 2011), Ohio (Ohio Department of Natural Resources, 2011), West Virginia (West Virginia Department of Environmental Protection, 2011), Texas (Railroad Commission of Texas, 2011), and Alaska (Alaska Department of Natural Resources, 2011).[72, 73]
- Urban areas, lakes, and ponds were removed from the study area, as mining is not expected to take place in these areas (U.S. Census Bureau, 2002; USGS, 2011b). However, some mining may take place under or adjacent to lakes and ponds, so the study area may slightly under-represent the areal extent of mining in this respect.

As described below, within the general study area, the analysis identifies a spatial and temporal boundary for considering cumulative impacts to each resource. Within that boundary, the analysis identifies past, present and reasonably foreseeable future actions that affect the same resources. Finally, the analysis summarizes the impacts of these actions in combination with the proposed action and considers their context and expected intensity in order to characterize potential cumulative impacts.

As established earlier in this document, the overall geographic scope for the analysis in this FEIS includes the seven major U.S. coal mining regions. The spatial boundary for cumulative impact analysis is defined by considering the point where the resource is no longer affected or the effects are no longer significant. This approach facilitates examination of actions that would impact the resources within a resource-specific, meaningful boundary, instead of an arbitrarily defined geographic boundary. The geographic

---

[72] The program description for the Alaska Coal Regulatory Program states that active mining currently only occurs near Healy, AK, in the Denali Borough.

[73] State-specific data for other states were examined where available, but contributed no additional counties beyond those listed by EIA.

scope of this analysis is at the coal region level.[74] Within this scope, the analysis determines the characteristics of each of the following resources as follows:

- **Water resources**: The analysis evaluates cumulative impacts within a "typical watershed" in each region. For example, considering number and types of streams, and the existing regulatory environment in each region.
- **Biological resources**: The analysis evaluates cumulative impacts at the regional level considering the typical land cover profile of a watershed in the region and the suite of species, including federally listed species, potentially present in any given watershed.
- **Geology, soils, and topography**: This cumulative impact analysis considers typical geologic, soil, and topographic characteristics at a regional level. For example, the existing regulatory environment (e.g., approximate original contour (AOC) requirements), the disposal of coal mine waste, and the treatment of excess spoil are among the factors considered to determine what is typical within a region.
- **Air quality**: The predominant effect of the rule on air quality and greenhouse gas emissions that is quantified in this EIS is the reduction in carbon dioxide (CO_2) emissions associated with the overall reduction in coal activity due to increased costs of coal production. In contrast to the other categories of environmental and economic impacts evaluated in this analysis, the benefits of reduced greenhouse gas emissions represent worldwide climate-related damages, independent of the geographic source of the emissions.
- **Socioeconomic impacts**: Socioeconomic conditions are characterized at the regional level based on county and state specific data on demography, income and employment, and taxes. Evaluation of cumulative impacts considers regional and national trends in these variables.
- **Land use, visual resources, and noise**: To evaluate the cumulative impacts this analysis considers typical land uses, visual resources, and noise levels existing before, during, and after mining operations at a regional scale.
- **Public health and safety**: Potential public health and safety impacts are characterized at regional and national levels for both water-quality and air-quality.
- **Archaeology, paleontology, and cultural resources**: In practice, evaluation of these resources occurs at the site-specific level. This analysis considers archaeological, paleontological, and cultural resources at a regional level, and notes that these would be relevant to the extent that these resources exist in mining locations.

[74] Where the spatial boundary is defined as regional, this refers to the seven major U.S. coal mining regions discussed previously. Where the spatial boundary is defined at a smaller scale, e.g., the watershed, local, or site-specific scale, the analysis was based on a general interpretation of normal circumstances and activities expected to occur in these areas rather than on any specific location. Air resources are evaluated at the national scale.

- **Recreation impacts**: Cumulative impacts consider types and levels of recreation occurring in typical watersheds in each region.

The temporal scope of the cumulative effects analysis was also determined based on the resource under consideration. The analysis presented here seeks to identify past, present, and reasonably foreseeable future actions that interact with the current actions. In some cases, relevant past actions may have been introduced in previous decades, but still have an enduring impact on the management or condition of the resource. The analysis considers only future actions that are reasonably foreseeable, i.e., those that have been explicitly proposed or which are approved but have not yet begun. The analysis generally avoids speculating on the trajectory or impact of rules and actions that are in formative stages of development.

The diverse set of affected resources, combined with the broad geographic and temporal scope of the SPR, makes cumulative impact analysis highly challenging. Indeed, simply identifying the full suite of past, present, and future actions affecting water resources in coal mining areas in the U.S. under the No Action Alternative and Action Alternatives is not feasible. For example, dozens, if not hundreds, of federal, state, and local laws and regulations could be perceived as being relevant to protecting the quality of water resources in streams affected by mining. Furthermore, an array of individual projects (e.g., dam construction, dredging), permitting decisions, and economic trends could further influence water quality. Identifying and accounting for all of these factors is not practical, and prediction of cumulative impacts based on such an approach would be speculative. Because it is practically infeasible to characterize every potentially relevant cumulative action in all coal-producing areas in the U.S., the analysis focuses on identifying the primary actions – particularly those that may combine with the Alternatives to produce cumulative effects. This approach is consistent with CEQ guidance, which states that "a cumulative effects analysis should 'count what counts,' not produce superficial analyses of a long laundry list of issues that have little relevance to the effects of the proposed action on eventual decisions" (CEQ, 1997).

4.5.2 Past, Present, and Reasonably Foreseeable Actions

A large set of past, present, and reasonably foreseeable future actions could interact with the Alternatives. These include:

- Past mining at sites that have not subsequently been reclaimed (e.g., abandoned mine lands);
- Regulatory actions directly related to mining and surface (e.g., stream) water quality;
- Rules that affect power plants that could affect coal demand;
- Overall trends in the coal mining industry and energy markets;
- Other trends that affect resources in the study area and that may alter the cumulative impacts of the proposed actions; and
- Other secondary regulatory actions.

Each of these actions has the potential to affect multiple resources. The subsections that follow review these actions and trends and associate them with each of the resource categories under consideration.

4.5.2.1 Regulatory Actions Related to Mining and Surface Water Quality

Several major federal and state laws and regulations currently protect streams from impacts associated with coal mining. First, the Surface Mining Control and Reclamation Act of 1977 (SMCRA) forms the legal backdrop to analyses in this FEIS. A description of relevant SMCRA provisions can be found in

Chapter 2, and specific aspects of SMCRA have been discussed here in Chapters 3 and 4. Apart from SMCRA, several additional statutes and regulations figure directly into the discussion of mining and its influence on surface water quality:

4.5.2.1.1 Past and Present Actions

- **SMCRA**: Title IV of the SMCRA (as implemented through regulations contained at 30 CFR Parts 870 – 887) establishes the abandoned mine reclamation program. This program provides for reclamation and restoration of land and water resources adversely affected by past coal mining, including but not limited to reclamation and restoration of abandoned surface mine areas, abandoned coal processing areas, and abandoned coal refuse disposal areas; sealing and filling abandoned deep mine entries and voids; planting of land adversely affected by past coal mining to prevent erosion and sedimentation; prevention, abatement, treatment, and control of water pollution created by coal mine drainage including restoration of stream beds, and construction and operation of water treatment plants; prevention, abatement, and control of burning coal refuse disposal areas and burning coal in situ; prevention, abatement, and control of coal mine subsidence; and establishment of self-sustaining, individual state administered programs to insure private property against damages caused by land subsidence resulting from underground coal mining in those states which have approved programs.

- **Clean Water Act**: Congress passed the Clean Water Act (CWA) in 1972 as amendments to the Federal Water Pollution Control Act. It is the primary legal foundation for restoring and maintaining the chemical, biological, and physical integrity of U.S. waters. Three components of the CWA are most relevant to coal mining operations:

    - **Section 303** of the CWA establishes water quality standards and calls for EPA and the states to identify impaired water bodies not attaining these standards. Those listed waters are subject to Total Maximum Daily Load (TMDL) procedures through which point and nonpoint pollutant sources are assigned allowable loadings of key pollutants. If near a listed stream, any new mining operation must demonstrate that proposed mining activity will not result in exceedance of the applicable TMDL.

    - **Section 402** of the CWA establishes the National Pollutant Discharge Elimination System (NPDES). The NPDES program issues permits to industrial point source and other pollutant dischargers (e.g., municipal stormwater systems). The permits contain numerical limits on the allowed concentration of pollutants; if monitoring indicates that the permit holder has exceeded the concentration (or overall loadings limits), the permit holder is subject to monetary penalties. Existing and new coal mines must obtain a NPDES permit.

    - **Section 404** of the CWA establishes the permit provisions governing dredging and filling of streams and wetlands. Under the program, any discharge of fill or dredge material must be authorized by a permit issued by the U.S. Army Corps of Engineers. Coal mining operations that place spoils in streams or wetlands must hold a Section

404 permit.[75] Section 404(e)(1) authorizes the Secretary of the Army to issue general permits for categories of activities involving discharges of dredged or fill material that, as a group, have only minimal impacts on the waters of the U.S. The USACE can issue these general permits (as well as individual permits) on a state, regional, or nationwide basis. The USACE refers to general permits issued on a nationwide basis as "Nationwide permits" (NWP). Current NWPs related to coal mining include NWP 21 related to surface mining, which the USACE reissued on February 21, 2012 (77 FR 10184), NWP 49 related to surface remining, and NWP 50 related to underground mining. These NWPs provides USACE authorization for the discharge of dredged or fill material into waters of the U.S. associated with coal mining activities. The USACE review under these permits is focused on the individual and cumulative adverse effects to the aquatic environment, and on determining appropriate mitigation should mitigation become necessary. The USACE review does not extend to the mining operation as a whole, unlike the SMCRA permit. Coal mining activities that impact waters subject to jurisdiction under CWA, and that do not meet the respective requirements of NWP 21 (surface coal mining), NWP 49 (surface coal remining), or NWP 50 (underground coal mining) would require an individual section 404 permit to proceed. Consideration of resources occurs under either an individual permit or a NWP, as required by the 404(b)(1) guidelines. The primary differences between the two processes are the extent of public review opportunities, the degree of administrative burden, and the amount of time involved in processing the permit.

- The CWA defines "navigable waters" to mean "waters of the United States, including the territorial seas" (*Id.* § 1362(7)). On June 29, 2015, following years of litigation over the term, the EPA and USACE issued a rule to clarify the scope of the definition of "waters of the United States." (80 Fed. Reg. 37053 (June 29, 2015)). The revised definition would narrow the scope of CWA jurisdiction such that fewer waters would be jurisdictional and would provide bright-line tests to reduce the number of instances where permitting authorities would need to make case-specific jurisdictional determinations (80 Fed. Reg. 37053 (June 29, 2015)). Multiple industry and environmental groups challenged the rule, and the Sixth Circuit issued an order staying the rule nationwide. The Sixth Circuit has set a briefing schedule that will conclude on February 17, 2017, and oral arguments will be scheduled as soon as practicable after briefing is complete.[76] In response to the Sixth Circuit's stay, the EPA and USACE resumed nationwide use of the agencies' prior regulations.[77] Thus,

[75] EPA issued guidance on implementation of the surface coal mining activities in Appalachia in 2011. The guidance was intended to clarify EPA's roles and expectations in permitting surface coal mining operations under Section 402 and 404 of the CWA. However, in 2013, this guidance was repealed and is not considered in this analysis.

[76] *OH, et al v. U.S. Army Corps of Engineers, et al*, (6th Cir. Case No. 15-3799, Case Management Order No. 2 dated 6/14/16).

[77] *See* EPA and Department of the Army Clean Water Rule Litigation Statement, https://www.epa.gov/cleanwaterrule/clean-water-rule-litigation-statement (last visited September 16, 2016).

the agencies' prior regulations form part of the existing regulatory environment for purposes of this EIS.

- **State Regulatory Authorities**: State regulatory programs implementing the CWA and SMCRA play an important role in managing the water quality impacts of mining. In areas where coal mining occurs outside of federal programs, state programs exist that manage coal mining activities and issue SMCRA permits. Some states (e.g., West Virginia) have developed policies that provide protections that may be more stringent than current SMCRA requirements.[78] Some state regulatory authorities currently have clauses in their programs directing authorities to adopt laws or regulations that are "no more stringent than" the federal SMCRA program. EPA authorizes state environmental agencies to administer components of the CWA. For example, nearly all states where coal mining occurs have approval to issue NPDES permits, or have a program in place that is pending approval.

4.5.2.1.2 Reasonably Foreseeable Future Actions

- **Coal Combustion Residues Rule**: OSMRE is currently developing a proposed rule that would establish specific regulations governing the placement of coal combustion residues on minesites, either as part of a mining operation regulated under SMCRA or as part of an abandoned mine land reclamation project approved under SMCRA. The rule responds to a 2006 National Research Council report that recommended the establishment of enforceable federal standards that provide explicit authority and minimum safeguards for the placement of coal combustion residues in mines.

- **Temporary Cessation of Operations Rule**: OSMRE is currently developing a proposed rule that would require regulatory authority approval of long-term temporary cessations of mining operations. The proposed rule also would establish a maximum duration of the temporary cessation.

- **Toxic Gases and Blasting Rule**: On February 20, 2015, the Director of OSMRE granted a petition from WildEarth Guardians requesting that OSMRE "promulgate a rule prohibiting the production of visible nitrogen oxide emissions during blasting at surface coal mining operations in order to protect public and mine worker health, welfare, and safety, and prevent injury to persons." See 80 FR 9256. OSMRE is currently developing a proposed rule.

- **Dam Safety Rule**: OSMRE is currently developing a proposed rule that would require development and maintenance of emergency action plans for impoundments classified as high hazard or significant hazard. The proposed rule also would revise the bond release requirements for coal slurry impoundments to ensure that the slurry has solidified to a nonflowable state before final bond release.

---

[78] In 2000, West Virginia developed its own policy on AOC and Excess Spoil Disposal (known as the "AOC+" policy), and Kentucky followed suit in 2009 with its Reclamation Advisory Memorandum (RAM) regarding the "Fill Placement Optimization Process" (known as the RAM 145 policy).

- **Self-Bonding Rule**: On September 7, 2016, the Director of OSMRE granted a petition from WildEarth Guardians requesting that OSMRE amend its self-bonding regulations to ensure that companies with a history of financial insolvency, and their subsidiary companies, are not allowed to self-bond coal mining operations. See 81 FR 61612. OSMRE is currently drafting a proposed rule that will better ensure the completion reclamation plans, guarantee that a self-bond applicant demonstrates a history of financial solvency and continuous operation sufficient for authorization to self-insure, and assure that surface coal mining operations are conducted to protect the environment.

4.5.2.2 Rulemakings Related to Coal-Fired Power Plants

Federal and state regulators have promulgated or are currently engaged in developing several rulemakings that will directly affect coal-fired electricity generating units (EGUs) (as well as other EGUs that are not coal fired). To the extent that these rules result in substitution of natural gas and other alternative fuels for coal, future coal demand could be less than it would have been in the absence of these rules. Such changes, in combination with other regulations that affect coal production directly or indirectly, including those affecting worker safety and others, may adversely impact coal jobs while benefiting the environment (as a result of decreased coal mining). As reviewed later in this section, these effects may combine with the Action Alternatives to produce noteworthy cumulative effects. While EPA has published a formal proposal for some of these rulemakings, others are at an earlier stage of development. These rules and their status as of 2016 are as follows:

4.5.2.2.1 Past Actions

- **Mercury and Air Toxics Standards**: Intended as a replacement for the Clean Air Mercury Rule, which was vacated in 2008, this rule establishes emission standards for mercury and other hazardous air pollutants from U.S. power plants.

- **Cross-state Air Pollution Rule (CSAPR)**: The Cross-state Air Pollution Rule (CSAPR) requires power plants in 27 states to reduce emissions that contribute to ambient ozone and/or fine particle pollution; EPA finalized the rule in 2011, and implementation began in 2012. In September 2016, the EPA finalized an update to the Cross-State Air Pollution Rule (CSAPR) for the 2008 ozone National Ambient Air Quality Standards (NAAQS); this rule will reduce summertime nitrogen oxides emissions from power plants in 22 states in the eastern U.S. Recent Supreme Court decisions verified EPA’s authority to regulate greenhouse gas emissions.

- **Cooling Water Intake Structures Rule**: EPA developed regulations under Section 316(b) of the CWA to limit injury and death of fish and other aquatic life caused by cooling water intake structures at existing power plants.

4.5.2.2.2 Present Actions

- **Coal Combustion Residuals (CCRs) Rule**: In June 2010, EPA proposed regulations under Resource Conservation and Recovery Act (RCRA) to address the risks from the disposal of CCRs generated from coal combustion at electric utilities and independent power producers. EPA published a final rule in the *Federal Register* on April 17, 2015 (80 FR 21302).

4.5.2.2.3 Reasonably Foreseeable Future Actions

- **Carbon Pollution New Source Performance Standards (NSPS) for Energy Generating Units (EGUs):** In August 2015, the EPA promulgated the Carbon Pollution Standards, which limit emissions of CO_2 from new, modified, and reconstructed fossil-fuel fired power plants.

- **Clean Power Plan**: In August 2015, the EPA promulgated Clean Power Plan, which established guidelines for reducing CO_2 emissions from existing fossil-fuel fired power plants. States are charged with developing plans that will meet the emission performance rates (or equivalent state goals). EPA and industry analysts anticipate that many of the reductions will be met through shifting generation to less carbon-intensive sources of energy. On February 9, 2016, the Supreme Court stayed implementation of the Clean Power Plan pending judicial review.

As is discussed below, most of these rulemakings focus on air quality improvement; the residuals rule and the cooling water rule target water and biological resource protection. In addition, all of them may have implications for the competitiveness of coal in broader energy markets.

4.5.2.3 Non-Regulatory Trends

Factors affecting the resources are not restricted to laws and regulations, but may also include economic trends, market factors, and litigation outcomes in the coal industry and other industries with intensive land uses.

4.5.2.3.1 Trends in Coal Markets and the Coal Industry

The Action Alternatives would interact with ongoing developments in the coal industry, possibly producing noteworthy cumulative effects on the resources under consideration. Importantly, industry employment impacts associated with the Action Alternatives would occur in the context of other industry trends.

Section 4.1 of this FEIS reviews the coal mining industry and discusses trends in production and markets. Major points include the following:

- Small changes in the electricity market can influence both short and long-term demand for domestic coal. As described in section 4.1, electricity demand growth in the U.S. historically was driven by economic and industrial activity, and weather. This has changed. There has effectively been no growth in electricity demand since 2007. This is due to a number of factors including a decline in industrial electricity demand, which was largely offset by growth in demand from the residential and commercial sectors. Also significant is lower demand due to energy efficiency and distributed generation. Energy efficiency means using less energy to provide the same service. The most often used examples are fluorescent lighting instead of traditional incandescent bulbs. Distributed generation is small-scale technologies that produce electricity close to the end users of power. The technologies including modular and renewable-energy generators, such as roof-top solar, that are often behind the meter meaning they are not counted as retail sales. In addition, in many states the excess behind the meter power is sold into the grid. In addition, there has been substantial growth in renewables, particularly wind in the western U.S. Between 2010 and 2015, 33 GWs of wind have been added to capacity. Electricity generation from wind increased from 94,654 GWH in 2010 to 190,926 GWH in 2015. The Production Tax Credits (PTC) incentivize wind producers to generate around the clock (when wind is available). As a result, wind power contributes to lower power prices as well. The PTC was extended in December 2015 until 2019 along with the Business Energy Tax Credit (ITC), which applies to construction and development of renewable technologies.

- The largest market for U.S. coal has been the power sector, typically accounting for 80 to 90 percent of total production in recent years (U.S. EIA 2016f; U.S. EIA 2016g). The increase in gas and renewable generation directly reduced coal generation and the resulting demand for coal. Coal consumed in the power sector was 955 million tons in 2010 and 769 million tons in 2015 (U.S. EIA, 2016h). Estimates for coal consumed in the power sector for 2016 range between 650 and 700 million tons (U.S. EIA, 2016h). In addition, during the period 2010 through 2015, 45.5 GW of coal-fired capacity was retired (EVA, 2016).
- The second largest market for U.S. coal has been exports. The export market has been cyclical, depending upon both the global supply and demand for coal and the relative strength of the U.S. dollar. During the 2011 to 2013 period, there was a substantial increase with U.S. coal exports exceeding 100 million tons in each of those years. The strong demand reflected growth in seaborne coal trade combined with a weak U.S. dollar which made U.S. coals competitive in the U.S. dollar-denominated global coal market. The positive outlook for exports of U.S. coals in 2011 and 2012 has faded due to several factors including supply growth from other countries to the global market, a relatively strong U.S. dollar which has reduced global coal prices, a weaker global market due to a slowdown in the Chinese economy, and the lack of progress in the development of west coast export terminals which would be required to increase in a meaningful way exports of western coal to Asian markets. The positive outlook could be restored if the U.S. dollar weakens relative to other currencies or there is reduced supply and/or increased demand in the global seaborne market for coal. The range in potential export levels is handled through the scenario analysis.
- Industries, such as steel, iron, and cement manufacture, rely on coal for energy. Thus, fluctuations in these markets can also cause changes in coal demand.
- Coal company consolidation has been a trend in recent years within the coal industry, and additional consolidation is possible, particularly in regions with declining production. The implications of consolidation are unclear.
- Throughout history, the regulatory environment surrounding the coal industry has fluctuated. This environment is likely to continue to experience changes in the coming years. Future regulations may impact production and demand in ways that are impossible to predict.

4.5.2.3.2 Other Land Use Trends

Trends in non-mining industries with intensive land uses also represent important actions that could affect cumulative outcomes. The importance of these land use trends for the subject resources is highly region-specific. Drawing on findings presented in Chapter 3, the analysis considers three key land use trends: forestry, agriculture/grazing, and growth/development.

4.5.2.3.2.1 Forestry Trends

Coal mining occurs in a variety of settings, but watersheds affected by coal mining are also commonly affected by forestry activities, particularly in the eastern U.S. (Louisiana Forestry Association, 2011; Piva and Cook, 2011; Texas Almanac, 2014). It is not uncommon for forestry and coal mining activities to occur in the same location as timber often needs to be removed to allow transport of coal mining equipment. Thus, trends in commercial forestry represent land use changes that could interact with the Alternatives to influence cumulative impacts on key resources. Most notably, forestry practices can affect water quality through pollutant runoff and sedimentation of streams. Likewise, the intensity and method of the forestry activities can influence the availability and quality of terrestrial wildlife habitat.

Coal regions where forestry is a significant land use include the following:

- Approximately 60 percent of land in the Appalachian Basin is deciduous forest and several large National Forests exist in the region. While trends vary by sub-region, some portions of the Appalachian Basin have seen increased timber harvests in recent years. For instance, West Virginia production of industrial roundwood roughly doubled from 1979 to 2007, totaling nearly 190 million cubic feet (Piva and Cook, 2011).

- In the Gulf Coast region, Mississippi and Louisiana have extensive commercial forestry operations. Forest products were the highest value crop harvested in Louisiana in 2010, worth over three billion dollars (Louisiana Forestry Association, 2011). In Mississippi, the timber harvest was valued at $1.1 billion in 2013 (Mississippi State University, 2014). In addition, the Texas timber industry is concentrated almost exclusively in the northeast portion of the state (near Louisiana), meaning that it is almost fully contained in the Gulf Coast coal region (Texas Almanac, 2014). The delivered value of Texas timber was roughly $500 million in 2011.

State forestry programs may promote best management practices (BMPs) that are intended to protect water resources, among other resources. For example, Tennessee's BMP guide recommends practices such as establishment of streamside buffer zones, soil stabilization through reforestation, and use of sediment control structures (Tennessee Department of Agriculture, 2003). In conjunction with the proposed action, these BMPs could reduce forestry impacts such as sedimentation and streamside vegetation removal.

4.5.2.3.2.2 Agriculture Trends

Agriculture, including crop cultivation and livestock operations, is a significant contributor to water quality impairment. In EPA's 2000 National Water Quality Inventory, states reported that agricultural nonpoint source pollution was the leading source affecting water quality in rivers and lakes. Runoff of nutrients from cropland can cause eutrophication and oxygen depletion in receiving waters, and excessive pesticide use can also contaminate surface and groundwater. Improperly managed livestock operations can allow nutrients and pathogens to contaminate surface and groundwater. Likewise, excessive grazing can lead to soil erosion and sedimentation of surrounding surface waters.

Coal regions where agriculture and grazing have the greatest potential to interact with mining to affect cumulative impacts include the following:

- Relative to the other coal-producing regions, the Illinois Basin has the greatest amount of cultivated cropland. Cropland accounts for over 48 percent of the land use in this coal region. Illinois had approximately 22 million acres of harvested cropland in 2012, roughly unchanged from 2007. The total value of all agricultural products sold in 2012 was about $17.2 billion, up significantly from 2007 when sales totaled $13.3 billion (USDA, 2014).

- Livestock grazing is common in several coal-producing regions. In the Western Interior region, pasture and grazing operations account for over 38 percent of the land use in Kansas and Oklahoma. Likewise, the Gulf Coast region is over 26 percent pastureland.

4.5.2.3.2.3 Land Use Change

Economic growth can introduce environmental stress that could affect resources in coal-producing regions. Most notably, population growth typically brings increased land clearing and conversion of unimproved lands or croplands to buildings, roads, and other infrastructure. These changes in the landscape reduce the habitat available for wildlife, thereby influencing biological resources. In addition, growth can greatly alter natural water cycles as surface and groundwater is withdrawn for consumptive use, treated, and discharged. Furthermore, urban land uses typically increase impervious surfaces, leading to increased stormwater runoff. This runoff can produce increased loadings of pollutants such as nutrients, sediment, and metals in waterways. As such, growth and urbanization has the potential to interact with coal mining practices to place greater stress on many resources, particularly surface water, groundwater, and biological resources.

Development can also occur through conversion of land that has been farmed for crops or livestock. Because agricultural runoff from agricultural practices may have degraded water quality in these areas, conversions of this type may have fewer adverse effects on local water quality than would conversions of unimproved land.

Population growth is the driver for the land use and water quality changes described above. The socioeconomic section of Chapter 3 describes demographic trends in the coal-producing regions. In the period from 2000 to 2010, the coal regions seeing the greatest growth tended to be those in western states. The Northern Rocky Mountains and Great Plains region showed a 21 percent growth in population during this period, making it the fastest growing coal region. Other rapidly growing regions include the Colorado Plateau and the Gulf Coast regions. In terms of 2010 population, the most populous coal regions are the Appalachian Basin and the Illinois Basin.

4.5.2.4 Other Regulatory Actions

In addition to the major actions and trends described above, numerous other actions have the potential to produce the types of additive or countervailing effects relevant to assessing cumulative effects. In particular, these may include state and local regulations and ordinances, which vary by location, as well as other federal actions that apply to particular activities at particular geographic locations. As noted, the geographic, temporal, and policy scope of the Alternatives is so great that care must be taken to ensure that additional laws and regulations are considered, while properly bounding the analysis. Relevant laws and regulations were identified through review of past coal mining EISs, other EISs, and on-line resources compiling laws and regulations applicable to coal mining (BIA, 2014). A brief description of each law or regulation is provided in the Table 4.5-1, which summarizes the actions and trends considered in the cumulative effects analysis.

4.5.2.5 Summary of Actions

Table 4.5-1 briefly summarizes all the actions and trends, both major and secondary, and identifies the resources that each action affects most directly. For each relevant resource/action combination, the table uses a positive sign ("+") to indicate that the action generally tends to benefit the resource, or a negative sign ("-") if the action is more likely to affect the resource adversely. It is important to note that the impact of each action/trend is complex and may have adverse as well as beneficial impacts on resources depending on the particular project or site. Thus, assigning a single positive or negative sign to an action will not fully capture the more nuanced effects of these actions/trends. For example, implementation of CWA initiatives may not universally result in beneficial impacts to biological resources; however, the general conclusion that improvements in water quality should benefit biological resources as well is reasonable for purposes of this analysis. Likewise, CWA initiatives may have negative effects on socioeconomic resources including employment demand. However, these initiatives may also have beneficial socioeconomic effects through increases in industry implementation-related employment demand and reduced pollution.

Table 4.5-1. Actions and Trends Considered in Cumulative Effects Analysis

Action/Trend	Status[1]	Relevance	Water	Bio-logical	Geo-logy	Air	Socio-economic	Land Use	Recrea-tion	Archeo-logical	Health
Clean Water Act, Section 303	P	Establishes water quality standards and identifies impaired waters.	+	+			-		+		+
Clean Water Act, Section 402	P	Establishes NPDES permit program for point source discharges to surface waters.	+	+			-		+		+
Clean Water Act, Section 404	P	Establishes permit system governing dredging and filling of streams and wetlands.	+	+			-				
Clean Water Rule	F	Increases the clarity of waterway definitions under the Clean Water Act waters of the U.S. definition related to tributaries, adjacent wetlands/waters, “other” waters, and exclusions.	+	+							
State Mining Regulations and Programs	P	State regulations may supplement SMCRA regulations.					-			+	+
OSMRE Coal Combustion Residue Rules	F	Would establish environmental protections when coal combustion residues are disposed at mines.	+	+							
OSMRE Temporary Cessation of Operations Rule	F	Would better define cessation of mining operations and limit delays in reclamation.	+	+	+			+	+		+
OSMRE Self-bonding Rule	P	Will better ensure the completion reclamation plans, guarantee that a self-bond applicant demonstrates a history of financial solvency and continuous operation sufficient for authorization to self-insure, and assure that surface coal mining operations are conducted to protect the environment.	+	+	+		-				
Clean Power Plan	P	Standards for limiting carbon dioxide emissions at power plants. Could affect coal demand.	+	+		+	-				
Carbon Pollution New Source Performance Standards (NSPS) for EGUs	P	Promulgated in August, 2015. Limits emissions of CO_2 from new, modified, and reconstructed fossil-fuel fired power				+	-				

Action/Trend	Status[1]	Relevance	Water	Bio-logical	Geo-logy	Air	Socio-economic	Land Use	Recrea-tion	Archeo-logical	Health
		plants.									
Mercury and Air Toxics Standards (MATS)	P	Establishes emission standards for mercury and other hazardous air pollutants from U.S. power plants. Could affect coal demand.				+	-				
Cross-State Air Pollution Rule (CSAPR)	P	Requires power plants to reduce emissions of particulates and ozone precursors. Could affect coal demand.				+	-				
Coal Combustion Residuals Rule (EPA)	P	Would establish new rules for disposal of ash from coal-fired power plants. Could affect coal demand.	+	+			-				
Cooling Water Intake Structures Rule	P	Establishes rules to limit injury to aquatic species during cooling water intake. Could affect coal demand.		+			-				
Coal Market Trends	P, F	Economic trends and market factors that may affect demand for coal. See text for details.					-				
Forestry Trends	P, F	Commercial timber harvesting can affect water quality, terrestrial wildlife habitat, and soil and erosion patterns.	-	-	-		+		-	-	
Agriculture and Grazing Trends	P, F	Cropping and livestock operations can affect soil erosion, nonpoint source runoff, and water quality.	-	-	-				-	-	
Land Use Change	P, F	Demographic changes and urban land uses can affect wildlife habitat, stormwater runoff, and water quality.	-	-			+	-	-	-	
Mine Improvement and New Emergency Response Act (2006)	P	Calls for mine-specific emergency response plans at underground mines. Could mitigate potential risk associated with increased underground mining.					-				+
Emergency Watershed Protection (EWP) Program administered by the Natural Resource Conservation Service under section 216 of P.L. 81-516	P	Undertakes emergency measures when flood, fire, drought, erosion, etc. cause a sudden impairment of the watershed. 2005 rule expanded the program to include procedures for sediment deposition restoration and conservation.	+	+	+			+	+	+	+
Endangered Species Act (ESA) of 1973	P	Provides for the protection and recovery of imperiled species and their habitat.		+							

Action/Trend	Status[1]	Relevance	Water	Bio-logical	Geo-logy	Air	Socio-economic	Land Use	Recrea-tion	Archeo-logical	Health
		Permitting and conduct of coal mining under SMCRA must be coordinated with ESA requirements.									
Federal Mine Safety and Health Act of 1977	P	Requires the Department of Labor's Mine Safety and Health to inspect mines for worker safety.					-				+
Safe Drinking Water Act (SDWA)	P	Main federal law that ensures the quality of drinking water in the U.S. EPA sets standards for regulating specific pollutants. Part 141 establishes health standards, maximum pollutant levels (MCLs) and MCL goals for public water systems. Part 143 establishes secondary MCLs for aesthetic standards for public waterway systems.	+								+
OSMRE's Abandoned Mine Land Reclamation Program		The Abandoned Mine Land Reclamation Program is OSMRE's largest program and one of OSMRE's primary responsibilities under SMCRA. Since SMCRA's enactment in 1977, the AML program has collected over $10.1 billion in fees from present-day coal production and distributed more than $7.6 billion in grants to states and tribes, mandatory distributions to three health care plans within the UMWA Funds and OSMRE's operation of the national program to reclaim land and waters damaged by coal mining before the law's passage.	+	+				+	+	+	+
BLM's Abandoned Mine Lands Program	P	Administered by the Bureau of Land Management, protects public safety and water quality by reducing the effects of abandoned hardrock mines. Objectives include restoration of fish and wildlife habitat.	+	+				+	+	+	+
Soil and Water Resources Conservation Act of 1977	P	Provides for the U.S. Department of Agriculture to possess information, technical expertise, and a system for	+	+	+			+		+	

Action/Trend	Status[1]	Relevance	Water	Bio-logical	Geo-logy	Air	Socio-economic	Land Use	Recrea-tion	Archeo-logical	Health
		conservation and use of soils, plants, woodlands, and watersheds.									
Wild and Scenic Rivers Act (WSR)	P	Protects rivers and riparian areas that possess important scenic, recreational, fish and wildlife, and geologic values.	+	+	+			+	+		
Forest Service Manual (FSM) 2520, Watershed Protection and Management	P	USFS's program for maintaining or improving watershed conditions in National Forests. Activities include monitoring, riparian management, floodplain management, and emergency response.	+	+	+				+	+	
Forest Service Manual (FSM) 2380, Forest Service Scenery Management System of 2003	P	Any long term impacts on USFS visual resources fall under these standards which require the use of best management practices (BMPs) to mitigate impacts; USFS may require that some areas be returned to planned visual quality objectives within a certain time frame.						+	+	+	
National Trail System Act	P	Provides for preservation of, public access to, travel within, and enjoyment of outdoor areas through a national trail system. Jointly managed by the Bureau of Land Management, National Park Service, and USFS.						+	+		
National Wildlife Refuge System Administration Act (NWRSA)	P	Legislation establishing the National Wildlife Refuge System overseen by the U.S. Fish and Wildlife Service.		+					+		
Wilderness Act of 1964	P	Legislation establishing the National Wilderness Preservation System managed by the Bureau of Land Management.	+	+	+				+	+	
Noise Control Act of 1972 and EPA Noise Control Regulations	P	Federal legislation for regulation of noise pollution in order to protect human health. Administered through noise control regulations originally promulgated by EPA and now overseen by state and local governments.						+			+

Action/Trend	Status[1]	Relevance	Water	Bio-logical	Geo-logy	Air	Socio-economic	Land Use	Recrea-tion	Archeo-logical	Health
State Water Quality Regulations (examples)											
Pennsylvania's "The Clean Streams Law" Act of 1937, P.L. 1987	P	Protects public health, animal and aquatic life, industrial use, and recreational use of water by regulating supply and quality of Pennsylvania waters.	+	+					+		+
Kentucky Wild Rivers Act of 1972	P	Establishes the Wild Rivers Program to protect and preserve the scenic, fish and wildlife, geological, cultural and recreational values of Kentucky rivers.	+	+					+	+	+
Ohio Coastal Nonpoint Pollution Control Program Plan 2000	P	Ohio's plan to reduce runoff from cropland, parking lots, lawns, mines, and septic systems into surface and groundwater.	+	+					+		+

1. "P" = Past/Present/Ongoing; "F" = Future.

It is essential to note that these designations do not indicate long-term anticipated trends in the quality or health of the resource. For instance, while a permit program such as NPDES may be designed to improve long-term water quality, the permits themselves explicitly allow the discharge of pollutants to water bodies. While the NPDES program may produce a long-term benefit relative to a scenario where discharges occur without regulatory controls, some pollution of surface water will continue. This same observation is true for several of the regulatory programs identified as past and present actions, including those related to filling and dredging (CWA Section 404), and air emissions.

4.5.3 Assessment of Cumulative Impacts by Resource

The following discussion describes the cumulative impacts of the Action Alternatives when combined with other past, present, and reasonably foreseeable future actions. Under the No Action Alternative, no further regulations or corrective measures in addition to those already in place would be implemented. The analysis recognizes that in most cases the contribution to the cumulative impacts for a given resource from implementing the Action Alternatives would be difficult to discern, at a broad programmatic level across the U.S., given the context and intensity of impacts from the other past, present, and future actions. In most situations, implementation of one of the Action Alternatives would likely help reduce long-term adverse impacts on the resource by providing a certain level of offsetting benefits. This is especially true when the Action Alternatives are considered in combination with other actions of similar intent (e.g., point source discharge permitting, river conservation initiatives, etc.).

Given the scope of the Action Alternatives, their cumulative effects are best considered in a qualitative framework. Table 4.5-2 addresses each affected resource, summarizing the likely cumulative effects. First, the table notes the direct and indirect effects that each Action Alternative has on the identified resources, as determined in the resource-specific sections of Chapter 4. The table then identifies the relevant set of past, present, and future actions associated with the resource, as discussed above. Finally, the table designates, for each Action Alternative, the likely cumulative effect. Essentially, the cumulative impact designation can be considered as the outcome of adding the direct and indirect effects of the Action Alternative to the impacts of a set of past, present, and reasonably foreseeable actions relevant to the resource. Adding these effects yields a basic characterization of potential cumulative impacts of all relevant actions on the resource. Each of the resource-specific subsections below applies this structure in considering cumulative effects.

The analysis designates several cumulative effect classifications:

- “Beneficial or countervailing cumulative effect” means that, in combination with other actions and trends, the Alternative is expected to result in either a net increase in beneficial impacts or a net reduction in adverse impacts to the resource.

- “Negative cumulative effect” means that, in combination with other actions and trends, the Alternative is expected to result in a net increase in adverse effects to the resource.

Notes for tables a through i:

[1] These findings are consistent with those reported in previous sections of this chapter.

[2] Negative effects anticipated from the Alternative in combination with other mining regulations, regulations on coal-fired power plants, and overall energy market trends. This finding includes an implicit assumption that increased environmental regulations may have an adverse impact on employment, which may not always be the case.

- "Neutral cumulative effect" means that, in combination with other actions and trends, the Alternative is expected to produce little or no discernible effect on the resource.

- "Indeterminate cumulative effect" means that the combined effect of the Alternative, in combination with other actions and trends, is difficult to characterize with confidence given the mix of countervailing influences.

4.5.3.1 Water Resources

4.5.3.1.1 No Action Alternative

Under the No Action Alternative, no further regulations or corrective measures in addition to those already in place would be implemented. Therefore, ongoing trends in water resources would continue. The annual quantity of coal demanded and associated production is anticipated to be approximately 10 percent lower in 2040 than in 2020 without implementation of the Alternatives (i.e., under the No Action Alternative). This reduction in production would reduce adverse impacts of ongoing coal mining activities on water resources under the No Action Alternative.

Population growth is a primary driver of water quality changes associated with land clearing and development, as well as overall resource use. The socioeconomic section of Chapter 3 describes demographic trends in the coal-producing regions. In the period from 2000 to 2010, the coal regions seeing the greatest growth tended to be those in western states. The Northern Rocky Mountains and Great Plains region showed a 21 percent growth in population during this period, making it the fastest growing coal region. Other rapidly growing regions include the Colorado Plateau and the Gulf Coast regions. In terms of 2010 population, the most populous coal regions are the Appalachian Basin and the Illinois Basin. These population growth pressures are likely to increase adverse impacts to water resources under the No Action Alternative.

Trends in forestry under the No Action Alternative would also affect water resources. Approximately 60 percent of land in the Appalachian Basin is deciduous forest and several large National Forests exist in the region. While trends vary by sub-region, some portions of the Appalachian Basin have seen increased timber harvests in recent years. For instance, West Virginia production of industrial roundwood roughly doubled from 1979 to 2007, totaling nearly 190 million cubic feet (Piva and Cook, 2011). In the Gulf Coast region, Mississippi and Louisiana have extensive commercial forestry operations. Forest products were the highest value crop harvested in Louisiana in 2010, worth over three billion dollars (Louisiana Forestry Association, 2011). In Mississippi, the timber harvest was valued at $1.1 billion in 2013 (Mississippi State University, 2014). In addition, the Texas timber industry is concentrated almost exclusively in the northeast portion of the state (near Louisiana), meaning that it is almost fully contained in the Gulf Coast coal region (Texas Almanac, 2014). The delivered value of Texas timber was roughly $500 million in 2011. State forestry programs may promote best management practices (BMPs) that are intended to protect water resources, among other resources. For example, Tennessee's BMP guide recommends practices such as establishment of streamside buffer zones, soil stabilization through reforestation, and use of sediment control structures (Tennessee Department of Agriculture, 2003). In conjunction with the proposed action, these BMPs could reduce forestry impacts such as sedimentation and streamside vegetation removal.

Trends in agriculture also influence water quality within the study area. Relative to the other coal-producing regions, the Illinois Basin has the greatest amount of cultivated cropland. Cropland accounts for over 48 percent of the land use in this coal region. Illinois had approximately 22 million acres of harvested cropland in 2012, roughly unchanged from 2007. The total value of all agricultural products sold in 2012 was about $17.2 billion, up significantly from 2007 when sales totaled $13.3 billion (USDA, 2014). Livestock grazing is common in several coal-producing regions. In the Western Interior region, pasture and grazing operations account for over 38 percent of the land use in Kansas and Oklahoma. Likewise, the Gulf Coast region is over 26 percent pastureland.

In concert with the above, efforts to improve water quality conditions under other OSMRE rules, such as the OSMRE's Abandoned Mine Lands Program, the CWA, the Wild and Scenic Rivers Act, the Natural Resources Conservation Service (NRCS) water protection program, as well as regional, state, local water quality improvement efforts, may continue to decrease ongoing adverse effects associated with coal mining, agriculture, forestry and residential and other commercial development activities on water resources under the No Action Alternative.

4.5.3.1.2 Action Alternatives

As discussed in Section 4.2.1, the direct and indirect effects of the Action Alternatives on water resources are expected to be beneficial (except in the case of Alternative 9 where impacts are Negligible). These benefits occur as a result of improved baseline data collection; the use of enhanced water quality monitoring; improved definitions of material damage to the hydrologic balance; identification of evaluation thresholds; reduced stream filling; improved streamside vegetative corridor practices; and limitations on approximate original contour (AOC) variances. While the mix and nature of these requirements varies across the Action Alternatives, all are designed to yield benefits to water quality.

Second, as discussed above, the suite of other relevant past, present, and reasonably foreseeable future actions is complex, but the past, ongoing, and reasonably foreseeable future regulatory and conservation initiatives generally represent measures designed to benefit water resources. These include CWA permit programs; mining rules intended to improve or expedite restoration activities; stream conservation and management initiatives; and forestry and agricultural programs designed to limit water quality impacts. Water quality also is influenced by non-regulatory factors, such as trends in commercial forestry, crop cultivation, livestock operations, and urbanization associated with population and economic growth. The cumulative impact assessment incorporates these trends and acknowledges that they could run counter to the beneficial influence of regulatory and conservation initiatives. This is particularly true at a regional or local level where a particular trend (e.g., rapid growth in commercial forestry) is especially pronounced. However, at a national level, the past, ongoing, and reasonably foreseeable future regulatory and conservation initiatives may mitigate the effect of specific trends adversely affecting water resources.

The Action Alternatives (excluding Alternative 9), in combination with other actions and trends, are likely to reduce adverse cumulative impacts on water resources. Therefore, Table 4.5-2 identifies the Alternatives as having a beneficial or countervailing cumulative effect, depending on local, regional, and site-specific factors. Alternative 9 is anticipated to have a neutral cumulative effect.

4.5.3.2 Biological Resources

4.5.3.2.1 No Action Alternative

Under the No Action Alternative, no further regulations or corrective measures in addition to those already in place would be implemented. Therefore, ongoing trends in biological resources would continue.

The annual quantity of coal demanded and associated production is anticipated to be approximately 10 percent lower in 2040 than in 2020 without implementation of the Alternatives (i.e., under the No Action Alternative). This reduction in production would reduce adverse impacts of ongoing coal mining activities on biological resources under the No Action Alternative.

Population growth is a primary driver of changes in biological resources associated with land clearing and development, as well as overall resource use. The socioeconomic section of Chapter 3 describes demographic trends in the coal-producing regions. In the period from 2000 to 2010, the coal regions seeing the greatest growth tended to be those in western states. The Northern Rocky Mountains and Great Plains region showed a 21 percent growth in population during this period, making it the fastest growing coal region. Other rapidly growing regions include the Colorado Plateau and the Gulf Coast regions. In terms of 2010 population, the most populous coal regions are the Appalachian Basin and the Illinois Basin. These population growth pressures are likely to increase adverse impacts to biological resources under the No Action Alternative.

Trends in forestry under the No Action Alternative would also affect biological resources. As noted above, approximately 60 percent of land in the Appalachian Basin is deciduous forest and several large National Forests exist in the region. While trends vary by sub-region, some portions of the Appalachian Basin have seen increased timber harvests in recent years. For instance, West Virginia production of industrial roundwood roughly doubled from 1979 to 2007, totaling nearly 190 million cubic feet (Piva and Cook, 2011). In the Gulf Coast region, Mississippi and Louisiana have extensive commercial forestry operations. Forest products were the highest value crop harvested in Louisiana in 2010, worth over three billion dollars (Louisiana Forestry Association, 2011). In Mississippi, the timber harvest was valued at $1.1 billion in 2013 (Mississippi State University, 2014). In addition, the Texas timber industry is concentrated almost exclusively in the northeast portion of the state (near Louisiana), meaning that it is almost fully contained in the Gulf Coast coal region (Texas Almanac, 2014). The delivered value of Texas timber was roughly $500 million in 2011. State forestry programs may promote best management practices (BMPs) that are intended to protect biological resources, among other resources. For example, Tennessee’s BMP guide recommends practices such as establishment of streamside buffer zones, soil stabilization through reforestation, and use of sediment control structures (Tennessee Department of Agriculture, 2003). In conjunction with the proposed action, these BMPs could reduce forestry impacts such as sedimentation and streamside vegetation removal.

Trends in agriculture also affect biological resources within the study area. As noted above, relative to the other coal-producing regions, the Illinois Basin has the greatest amount of cultivated cropland. Cropland accounts for over 48 percent of the land use in this coal region. Illinois had approximately 22 million acres of harvested cropland in 2012, roughly unchanged from 2007. The total value of all agricultural products sold in 2012 was about $17.2 billion, up significantly from 2007 when sales totaled $13.3 billion

(USDA, 2014). Livestock grazing is common in several coal-producing regions. In the Western Interior region, pasture and grazing operations account for over 38 percent of the land use in Kansas and Oklahoma. Likewise, the Gulf Coast region is over 26 percent pastureland.

In concert with the above, efforts to improve biological conditions, such as, water quality programs; mining rules intended to improve or expedite restoration activities; habitat conservation and management initiatives; and forestry and agricultural programs designed to conserve watershed integrity may continue to improve conditions under the No Action Alternative.

4.5.3.2.2 Action Alternatives

As discussed in Section 4.2.2, the direct and indirect effects of the Action Alternatives on biological resources are expected to be beneficial (except in the case of Alternative 9 where impacts are Negligible). Requirements related to expanded data collection, improved monitoring, materials damage definitions, and evaluation levels are expected to benefit instream and streamside habitat, as well as the species dependent upon that habitat. Furthermore, restrictions on activities in or near streams as well as improvements to postmining restoration would benefit terrestrial and aquatic habitat.

As noted above, the suite of past, present, and reasonably foreseeable future actions affecting biological resources is similar to those noted for water resources. These include water quality programs; mining rules intended to improve or expedite restoration activities; habitat conservation and management initiatives; and forestry and agricultural programs designed to conserve watershed integrity. Biological resources are influenced by non-regulatory factors, such as trends in commercial forestry and land use changes associated with increased population and urbanization. The cumulative impact assessment incorporates these trends and acknowledges that they could run counter to the beneficial influence of regulatory and conservation initiatives. This is particularly true at a regional or local level where a particular trend (e.g., rapid growth in commercial forestry) may be especially pronounced. However, at a national level, the past, ongoing, and reasonably foreseeable future regulatory and conservation initiatives likely mitigate the effect of specific trends affecting biological resources.

The Action Alternatives (excluding Alternative 9), in combination with other actions and trends, are likely to reduce anticipated adverse cumulative impacts on biological resources. Therefore, the analysis designates the Alternatives as having a beneficial or countervailing cumulative effect, depending on local, regional, and site-specific factors. Alternative 9 is anticipated to have a neutral cumulative effect.

4.5.3.3 Geology, Soils, and Topography

4.5.3.3.1 No Action Alternative

Under the No Action Alternative, no further regulations or corrective measures in addition to those already in place would be implemented. Therefore, ongoing trends in geology, soils, and topography would continue. The annual quantity of coal demanded and associated production is anticipated to be approximately 10 percent lower in 2040 than in 2020 without implementation of the Alternatives (i.e., under the No Action Alternative). This reduction in production would reduce adverse impacts of ongoing geology, soils, and topography under the No Action Alternative.

Population growth is a primary driver of disturbances to topography, geology, and soils associated with land clearing and development. As stated above, in the period from 2000 to 2010, the coal regions seeing the greatest growth tended to be those in western states. The Northern Rocky Mountains and Great Plains region showed a 21 percent growth in population during this period, making it the fastest growing coal region. Other rapidly growing regions include the Colorado Plateau and the Gulf Coast regions. In terms of 2010 population, the most populous coal regions are the Appalachian Basin and the Illinois Basin. These population growth pressures are likely to increase disturbances to topography, geology, and soils under the No Action Alternative.

Trends in forestry under the No Action Alternative would also affect topography, geology, and soils, particularly as forest cover influences runoff. Approximately 60 percent of land in the Appalachian Basin is deciduous forest and several large National Forests exist in the region. While trends vary by sub-region, some portions of the Appalachian Basin have seen increased timber harvests in recent years. For instance, West Virginia production of industrial roundwood roughly doubled from 1979 to 2007, totaling nearly 190 million cubic feet (Piva and Cook, 2011). In the Gulf Coast region, Mississippi and Louisiana have extensive commercial forestry operations. Forest products were the highest value crop harvested in Louisiana in 2010, worth over three billion dollars (Louisiana Forestry Association, 2011). In Mississippi, the timber harvest was valued at $1.1 billion in 2013 (Mississippi State University, 2014). In addition, the Texas timber industry is concentrated almost exclusively in the northeast portion of the state (near Louisiana), meaning that it is almost fully contained in the Gulf Coast coal region (Texas Almanac, 2014). The delivered value of Texas timber was roughly $500 million in 2011. State forestry programs may promote best management practices (BMPs) that are intended to protect water resources, among other resources. For example, Tennessee's BMP guide recommends practices such as establishment of streamside buffer zones, soil stabilization through reforestation, and use of sediment control structures (Tennessee Department of Agriculture, 2003). In conjunction with the proposed action, these BMPs could reduce forestry impacts such as sedimentation and streamside vegetation removal.

Trends in agriculture also influence topography, geology, and soils within the study area. Relative to the other coal-producing regions, the Illinois Basin has the greatest amount of cultivated cropland. Cropland accounts for over 48 percent of the land use in this coal region. Illinois had approximately 22 million acres of harvested cropland in 2012, roughly unchanged from 2007. The total value of all agricultural products sold in 2012 was about $17.2 billion, up significantly from 2007 when sales totaled $13.3 billion (USDA, 2014). Livestock grazing is common in several coal-producing regions. In the Western Interior region, pasture and grazing operations account for over 38 percent of the land use in Kansas and Oklahoma. Likewise, the Gulf Coast region is over 26 percent pastureland.

In concert with the above, efforts to decrease runoff of topsoil, actions such as erosion control programs, watershed protection programs, and habitat conservation programs seek to reduce adverse impacts of land development activities under the No Action Alternative.

4.5.3.3.2 Action Alternatives

As discussed in Section 4.2.3, the direct and indirect effect of the Action Alternatives on topography, geology, and soils is expected to be beneficial, except in the case of Alternatives 6 and 9 for which impacts are Negligible. Restrictions on activities in or near streams (e.g., mining through streams, spoil management) as well as limitations on AOC variances and improved surface configuration techniques would have direct benefits for natural topography and geological resources under most of the Action Alternatives. Likewise, requirements for improved topsoil management and revegetation would benefit this resource category directly. Requirements related to improved monitoring, material damage to the hydrologic balance definitions, and evaluation thresholds are expected to indirectly benefit geology and soil resources.

As stated above, for geological resources, the relevant past, present, and reasonably foreseeable future actions include erosion control programs, watershed protection programs, and habitat conservation programs. Geological resources also are influenced by non-regulatory factors, such as land use activities with extensive impacts on soils; these include commercial forestry, agriculture, and livestock grazing. In some coal-producing regions, these non-regulatory activities may partially counteract the beneficial influence of regulatory and soil conservation initiatives.

Overall, most of the Action Alternatives, in combination with other past, present, and reasonably foreseeable future actions and trends, are likely to reduce adverse cumulative impacts on geology, soils, and topography. Therefore, the analysis designates the Alternatives as having a beneficial or countervailing cumulative effect, depending on local, regional, and site-specific factors. Alternatives 6 and 9 are anticipated to have Negligible direct implications for geology, soils, and topography; therefore, the analysis classifies the cumulative impact as neutral.

4.5.3.4 Air Quality, Greenhouse Gas Emissions, and Climate Change

4.5.3.4.1 No Action Alternative

Under the No Action Alternative, no further regulations or corrective measures in addition to those already in place would be implemented. Therefore, ongoing trends in air quality, greenhouse gas emissions, and climate change would continue. The annual quantity of coal demanded and associated production is anticipated to be approximately 10 percent lower in 2040 than in 2020, even without implementation of the Alternatives (i.e., under the No Action Alternative). This reduction in production would reduce adverse impacts of air impacts associated with coal mining activities under the No Action Alternative.

A multitude of other past, present, and reasonably foreseeable future actions affect air quality and greenhouse gas emissions. Coal mining generally negatively affects air quality due to air emissions emanating from vehicle engines or explosives detonation, erosion and wind transport of dust, and release of fugitive methane emissions during mining activities. In a national-scope rulemaking such as the SPR, however, numerous other regulatory and non-regulatory actions influence air quality. While some air quality issues are local (toxic releases during blasting activities), others, such as greenhouse gas emissions and their relationship to climate change, have implications at the global scale. Air pollutant emissions are generally regulated and managed at both national and local scales, to minimize the effects of coal mining activity on air quality and global climate change. The effects of coal mining and coal combustion on air pollutant emissions are primarily regulated under the Clean Air Act; additionally, performance standards targeting reducing toxic emissions from blasting is managed under section 515 of SMCRA (30 U.S.C. §1265). Furthermore, permit programs for stationary sources, including federal requirements and state variations on those requirements, affect emissions of a range of pollutants. Regulations are also emerging to address limiting carbon emissions from power plants. Additional programs focused on promoting the recovery and use of coal mine methane may further reduce mining-related air pollutant emissions. On the other hand, continued population and economic trends will greatly affect air quality in any given region. Increased economic growth, population growth, expansion of road and highway systems, residential and commercial construction, and numerous other factors will affect air quality outcomes. A comprehensive accounting of factors affecting air quality in the coal regions under the No Action Alternative is beyond the scope of this analysis.

4.5.3.4.2 Action Alternatives

As discussed in Section 4.2.4, the Action Alternatives are anticipated to have Minor Beneficial (Alternatives 2 through 8) or Negligible (Alternative 9) implications for air quality at the national scale. Implementation of individual elements of the Action Alternatives may have either beneficial or adverse effects on air quality. On the beneficial side, the Action Alternatives may increase terrestrial carbon sequestration potential due to reforestation and streamside vegetative corridor requirements of Action Alternatives (except for Alternative 9) and reduce fugitive methane emissions from coal extraction due to reductions in overall production levels (with the exception of Alternatives 2 and 9). However, requirements for improved spoils management and surface configuration, as well as limits on AOC variances, may increase the use of equipment and vehicles to haul materials and therefore marginally increase greenhouse gas emissions from these sources. These potential adverse effects are, however, most likely neutral to minor and outweighed by the benefits of increased terrestrial carbon sequestration and reduced methane emissions. While data are not available to quantify the net effect of the Action Alternatives on emissions or ambient air quality, the net effects to air quality, greenhouse gas emissions, and climate change are likely to be Minor Beneficial at the national scale (with the exception of Alternative 9).

As stated above, a multitude of other past, present, and reasonably foreseeable future actions affect air quality and greenhouse gas emissions. The effects of coal mining and coal combustion on air pollutant emissions are primarily regulated under the Clean Air Act; additionally, performance standards targeting reducing toxic emissions from blasting is managed under section 515 of SMCRA (30 U.S.C. §1265). Furthermore, permit programs for stationary sources, including federal requirements and state variations on those requirements, affect emissions of a range of pollutants. Regulations are also emerging to address limiting carbon emissions from power plants. Additional programs focused on promoting the recovery and use of coal mine methane may further reduce mining-related air pollutant emissions. On the other hand, continued population and economic trends will greatly affect air quality in any given region. Increased economic growth, population growth, expansion of road and highway systems, residential and commercial construction, and numerous other factors will affect air quality outcomes. A comprehensive accounting of factors affecting air quality in the coal regions is beyond the scope of this analysis.

Overall, the cumulative air quality impact of the Action Alternatives, in combination with other past, present, and reasonably foreseeable future actions and trends such as those described above, is beneficial or countervailing, depending on local, regional, and site-specific factors. While the Action Alternatives (excluding Alternative 9) have Minor Beneficial impacts, the complexity of other actions and trends make it difficult to predict with confidence the combined effect on air resources. Alternative 9 is anticipated to have a neutral cumulative effect.

4.5.3.5 Socioeconomic Conditions

4.5.3.5.1 No Action Alternative

Under the No Action Alternative, no further regulations or corrective measures in addition to those already in place would be implemented. Therefore, ongoing trends in socioeconomic conditions would continue.

The annual quantity of coal demanded and associated production is anticipated to be approximately 10 percent lower in 2040 than in 2020 without implementation of the Alternatives (i.e., under the No Action Alternative). In particular, the Colorado Plateau, Appalachian Basin, and Northern Rocky Mountain and Great Plains regions are forecasted to have the largest production decreases in coal production, respectively. This reduction in production would be expected to have adverse impacts on localized socioeconomics conditions, to the extent that reductions in coal production also reduce coal mining employment and associated income. Reduced coal production volume would also reduce tax collections by regional governments. These decreases could result in depressed localized property values, and could result in adverse impacts to quality of life in communities that are dependent on coal production. However, property values also have the potential to increase as aesthetics improve in localized areas. Reduced noise and impacts to visual resources could also lead to benefits to quality of life in some areas, particularly if some areas become more attractive for recreational activities under the No Action Alternative.

4.5.3.5.2 Action Alternatives

As discussed in Section 4.3.1, at the national level, the Action Alternatives (excluding Alternative 9) are expected to produce Minor or Moderate Adverse impacts on the coal mining industry and the communities that depend upon it. Alternative 9 is expected to have Negligible impacts on socioeconomic conditions. The adverse effects primarily stem from anticipated job losses associated with decreased production, particularly in the Appalachian Basin, the Illinois Basin, and the Northern Rocky Mountains and Great Plains regions. Furthermore, the analysis shows the potential for reduced growth in severance tax collections over time. While these impacts are forecasted for all the Action Alternatives (except Alternative 9), they are most prevalent under Alternative 2.

The cumulative effects analysis considers the direct socioeconomic impacts of the rule and its alternatives in combination with various other trends and actions. Relevant actions include regulations with a direct effect on coal mining, as well as actions and trends that are likely to affect the demand for coal over time. For instance, established mining safety rules may continue to affect the profitability of mining while forthcoming rules on greenhouse gas emissions from coal-fired power plants may encourage a transition away from coal to substitute fuels. These changes are occurring in the context of other energy sector trends such as decreasing natural gas prices resulting from growth in domestic production. On balance, the coal mining industry faces economic and regulatory challenges in the domestic market.

As discussed in Section 3.14 coal mining accounts for 0.06 percent of national employment and 0.1 percent of national income (U.S. Census Bureau, 2014; U.S. EIA, 2015a). For context, EIA estimates that 2014 coal industry employment was approximately 75,000 employees (U.S. EIA, 2016a). This analysis projects that coal industry employment will decrease by over 7,000 full-time equivalents (FTEs) under baseline conditions from 2020 to 2040. This decrease in employment demand is consistent with the declining demand for U.S. coal from retiring coal-fired power plants and is expected to occur primarily in the Appalachian Basin, the Illinois Basin, and the Northern Rocky Mountains and Great Plains regions. The following summary of expected effects helps to illustrate anticipated impacts:

- Under Alternative 2, annual impacts to production-related employment are expected to range from a reduction in demand for 850 FTEs to a reduction of 28 across all regions, with an average reduction in annual demand of 270 FTEs.[79] Annual impacts to industry implementation-related employment are expected to range from a gain of 530 FTEs to a gain of 690 across all regions, with an average increase in annual demand of 620 FTEs;

- Under Alternative 3, annual impacts to production-related employment are expected to range from a reduction in demand for 650 FTEs to a reduction of two across all regions, with an average reduction in annual demand of 180 FTEs. Annual impacts to industry implementation-related employment are expected to range from a gain of 360 FTEs to a gain of 460 across all regions, with an average increase in annual demand of 420 FTEs;

- Under Alternative 4, annual impacts to production-related employment are expected to range from a reduction in demand for 580 FTEs to a reduction of 11 across all regions, with an average reduction in annual demand of 150 FTEs. Annual impacts to industry implementation-related employment are expected to range from a gain of 88 FTEs to a gain of 120 across all regions, with an average increase in annual demand of 100 FTEs;

- Under Alternative 5, annual impacts to production-related employment are expected to range from a reduction in demand for 390 FTEs to a reduction of five across all regions, with an average reduction in annual demand of 100 FTEs. Annual impacts to industry implementation-related employment are expected to range from a gain of 160 FTEs to a gain of 210 across all regions, with an average increase in annual demand of 190 FTEs;

- Under Alternative 6, annual impacts to production-related employment are expected to range from a reduction in demand for 340 FTEs to an increase of seven across all regions, with an average reduction in annual demand of 86 FTEs. Annual impacts to industry implementation-related employment are expected to range from a gain of 230 FTEs to a gain of 320 across all regions, with an average increase in annual demand of 270 FTEs;

- Under Alternative 7, annual impacts to production-related employment are expected to range from a reduction in demand for 580 FTEs to an increase of one across all regions, with an average reduction in annual demand of 170 FTEs. Annual impacts to industry implementation-related employment are expected to range from a gain of 220 FTEs to a gain of 280 across all regions, with an average increase in annual demand of 250 FTEs;

- Under Alternative 8 (Preferred), annual impacts to production-related employment are expected to range from a reduction in demand for 510 FTEs to a reduction of three across all regions, with an average reduction in annual demand of 120 FTEs. Annual impacts to industry implementation-related employment are expected to range from a gain of 240 FTEs to a gain of 310 across all regions, with an average increase in annual demand of 280 FTEs; and

---

[79] The range of annual impacts to employment represents the minimum and maximum effect in any year in the study period. The average effect is the average annual effect on employment of the Alternative over the 21 year study period.

- Under Alternative 9, no changes in either production-related or industry implementation-related annual employment are expected.

While the socioeconomic implications of the Action Alternatives range from minor to major depending on the region and alternative, these impacts would be added to existing and anticipated adverse conditions in the coal mining industry and could exacerbate these declining conditions. Therefore, the cumulative impact of the Action Alternatives (excluding Alternative 9), in combination with other actions and trends, is classified as negative. Alternative 9 is anticipated to have a neutral cumulative effect.

4.5.3.6 Land Use, Utilities, Infrastructure, Visual Resources, and Noise

4.5.3.6.1 No Action Alternative

Under the No Action Alternative, no further regulations or corrective measures in addition to those already in place would be implemented. Therefore, ongoing trends in land use, utilities, infrastructure, visual resources, and noise would continue. The annual quantity of coal demanded and associated production is anticipated to be approximately 10 percent lower in 2040 than in 2020 without implementation of the Alternatives (i.e., under the No Action Alternative). This reduction in production would reduce adverse impacts of ongoing coal mining activities on land uses under the No Action Alternative.

Reduced coal production would reduce adverse impacts to land use, reduce demands on utilities, and infrastructure, reduce adverse impacts to visual resources, and reduce noise in coal mining regions under the No Action Alternative.

In concert with the above, efforts to improve land use, utilities, infrastructure, visual resources, and noise conditions under the EPA Noise Control Regulations, the EWP, the FSM, and regional growth and development trends, as well as regional, state, local mine reclamation efforts, may continue to improve land use conditions in localized areas under the No Action Alternative.

4.5.3.6.2 Action Alternatives

As discussed in Section 4.3.2, the Action Alternatives are anticipated to have either Minor Beneficial or Negligible impacts on land use, utilities, infrastructure, visual resources, and noise. Minor Beneficial outcomes are anticipated for all Action Alternatives except 6 and 9 and are achieved primarily as a result of forecasted reductions in coal production and/or increased underground production. These changes could limit land clearing, landscape alteration, and noise impacts to a minor degree, particularly in the Appalachian Basin and Illinois Basin regions.

As with air impacts, a multitude of other past, present, and future actions could affect land use, utilities, infrastructure, visual resources, and noise in the coal-producing regions. This analysis explicitly accounts for several national conservation programs and noise control regulations that could influence cumulative effects. However, the scope of the Action Alternatives and the diverse collection of landscape and aesthetic considerations in this resource category render a full accounting of possible influences impossible. For instance, local land use and noise ordinances will influence key outcomes. Furthermore, the land clearing and construction activities that influence land use, infrastructure, and visual resources are themselves the result of complex local trends. Increased economic growth, population growth, transportation demand, housing demand, and numerous other factors play a role in overall impacts on this category of resources.

While the Action Alternatives have Negligible or Minor Beneficial direct impacts, the complexity of other past, present, and reasonably foreseeable future actions and trends make it difficult to predict with confidence the combined effect on land use, utilities, infrastructure, visual resources, and noise. Therefore, the analysis designates the cumulative effect as indeterminate. Alternative 9 is anticipated to have a neutral cumulative effect.

4.5.3.7 Public Health and Safety

4.5.3.7.1 No Action Alternative

Under the No Action Alternative, no further regulations or corrective measures in addition to those already in place would be implemented. Therefore, ongoing public health and safety trends would continue. The annual quantity of coal demanded and associated production is anticipated to be approximately 10 percent lower in 2040 than in 2020 without implementation of the Alternatives (i.e., under the No Action Alternative). This reduction in production would reduce adverse impacts of ongoing coal mining activities on water resources under the No Action Alternative.

Water and air quality are primary drivers of public health changes in coal mining regions. Arsenic, selenium, and sulfates are drinking water pollutants found to be elevated near mining regions. Of these pollutants, arsenic appears to be the most concerning as studies have demonstrated that inorganic arsenic in drinking water may play a significant role in cancers, primarily bladder cancers (Borak, 2007; Shiber, 2005). Surface mining has resulted in elevated levels of arsenic in drinking water in some coal mining areas. It is possible that some areas may experience reductions in arsenic exposure in drinking water as coal production decreases under the No Action Alternative. Although public tap water is regulated for arsenic concentrations, users of private wells may benefit from reductions in arsenic concentrations.

Trends in air quality under the No Action Alternative would also affect overall public health in coal mining regions. In particular, coal dust may be associated with nonmalignant lung disease, lung cancer, and gastric cancer. Additionally, coal mining contributes to rising greenhouse gas emissions, which has negative public health impacts from both ambient air quality and global warming. Due to forecasted decreases in production levels, air quality for adjacent communities may improve due to a lower overall exposure to coal dust and particulate matter.

In concert with the above, efforts to improve public health under the Federal Mine Safety and Health Act, the Abandoned Mine Lands Program, state mining and water quality regulations, the CWA, as well as regional, state, local mine safety and pollution improvement efforts, may continue to improve conditions in localized areas related to causes such mining safety, drinking and surface water quality, and mine reclamation.

4.5.3.7.2 Action Alternatives

Potential public health benefits from improved drinking water for all Action Alternatives, except for Alternative 9, lead to the net direct effects to be classified as beneficial or countervailing for Alternatives 2 through 8 (Preferred).

A variety of other actions influence outcomes with respect to mining safety and public health. State and federal mining safety regulations are designed to limit both the risk of chronic illness (e.g., respiratory conditions) as well as catastrophic outcomes (e.g., mine collapse). Litigation focusing on miner health and safety may further refine and extend existing regulations. Rules and actions governing general public health are obviously numerous, with the most relevant focusing on drinking water protection, surface water quality protection, and reclamation of abandoned mines. Beyond these actions, numerous other public health programs exist (e.g., vaccination programs, smoking cessation programs, counseling programs, etc.) and would affect the well-being of citizens living in the coal-producing regions.

The Action Alternatives, in combination with other past, present, and reasonably foreseeable future actions and trends, are likely to reduce adverse cumulative impacts on public health and safety. Therefore, this analysis identifies the Alternatives (excluding Alternative 9) as having a beneficial or countervailing cumulative effect. Alternative 9 is anticipated to have a neutral cumulative effect.

4.5.3.8 Archaeology, Paleontology, and Cultural Resources

4.5.3.8.1 No Action Alternative

Under the No Action Alternative, no further regulations or corrective measures in addition to those already in place would be implemented. Therefore, ongoing trends in archaeology, paleontology and cultural resources would continue. For example, adverse effects to cultural resources that occur as part of development activities would continue under the No Action. Under the No Action Alternative, a fairly stringent set of regulations are in place which attempt to avert and mitigate impacts to these resources where they occur.

4.5.3.8.2 Action Alternatives

As presented in Section 4.3.5, all Action Alternatives are expected to have Negligible impacts on archaeology, paleontology, and cultural resources on both the regional and national level. However, to the extent that any particular element of an Alternative reduces the extent of ground disturbance associated with mining, it would also reduce the disturbance of cultural resources located within that area. Therefore cultural resources may benefit from some or all of the rule elements.

Other regulatory actions that occurred in the past, present, or are expected to occur in the future may also affect the archaeological, paleontological, and cultural resources of a specific area. A number of federal regulations have been put in place to protect these resources, such as the Antiquities Act of 1906, the Paleontological Resources Preservation Act of 2009, and the National Historic Preservation Act. Additionally, state mining regulations and programs that supplement SMCRA may benefit these resources to the extent that they identify areas which contain these resources as unsuitable for mining practices.

When considered together, the Negligible direct effect of all the Action Alternatives and the other past, present, and reasonably foreseeable future actions and trends that affect cultural resources are anticipated to have a neutral cumulative effect on these resources, across all Alternatives.

4.5.3.9 Recreation

4.5.3.9.1 No Action Alternative

Under the No Action Alternative, no further regulations or corrective measures in addition to those already in place would be implemented. Therefore, ongoing trends in recreation would continue. The annual quantity of coal demanded and associated production is anticipated to be approximately 10 percent lower in 2040 than in 2020 without implementation of the Alternatives (i.e., under the No Action Alternative). This reduction in production would reduce adverse impacts of ongoing coal mining activities on recreational activities under the No Action Alternative.

Recreational activities, including hunting, wildlife viewing, trail use, boating, and fishing, may occur on both public and private lands within the study area. Public lands, including federal, state, and locally managed lands, are often popular destinations for recreators due to the relatively natural and undeveloped quality of those lands. In addition, private lands are also used for recreation. The Illinois Basin and Appalachian Basins have the highest percent of the study protected in federal, state, local, or private conservation areas with 24 and 18 percent of land area protected respectively. The states intersecting the coal regions with the highest visitation rates in terms of hunting, fishing, and wildlife viewing days were Indiana and Pennsylvania.

Future reductions in production may allow for or encourage increases in recreational activities, as well as increase the relative value that is placed on recreation activities as the quality of natural land may improve. In concert with the above, efforts to improve recreation conditions under the CWA, the Wild and Scenic Rivers Act, the Forest Service Manual, the National Wildlife Refuge System Administration Act, and the National Trail Systems Act, as well as regional, state, local recreation improvement efforts, may continue to improve conditions in localized areas related to causes such as park management and water quality under the No Action Alternative.

4.5.3.9.2 Action Alternatives

The analysis presented in Section 4.3.3 determined that the Action Alternatives would likely have beneficial implications for recreational resources (except in the case of Alternative 9 which has Negligible impacts). These beneficial impacts accrue to instream recreational activities such as fishing and swimming, which are enhanced as a result of anticipated water quality improvements. Terrestrial recreational resources are also enhanced through proposed improvements in spoil management, surface configuration, reforestation, and wildlife protection.

Other past, present, and future actions to protect and enhance recreational resources are myriad. Conservation programs such as Wild and Scenic Rivers, the National Trails System, and the National Wildlife Refuge system have explicit recreational objectives. Likewise, water quality regulations recognize recreational objectives and expressly classify waters as fishable or swimmable. Apart from these relatively recent actions, the U.S. has a long historical tradition of designating, protecting, and enhancing recreational resources through the National Park System and National Forests; likewise, states have designated numerous other recreational areas through state parks systems. Collectively, these actions work to preserve and expand access to recreational resources.

The Action Alternatives, in combination with other past, present, and reasonably foreseeable future actions and trends, are likely to reduce adverse cumulative impacts on recreational resources. Therefore, this analysis identifies the Alternatives (excluding Alternative 9) as having a beneficial or countervailing cumulative effect. Alternative 9 is anticipated to have a neutral cumulative effect.

4.6 Irreversible and Irretrievable Commitments of Resources and Adverse Environmental Effects Which Cannot Be Avoided

This section of Chapter 4 identifies resource commitments that could be irreversible or irretrievable as a result of the Action Alternatives, and it describes potential adverse environmental effects which cannot be avoided. This section is organized as follows:

- First it describes the NEPA requirements of "irreversible or irretrievable commitments of resources" and "adverse environmental effects which cannot be avoided";
- Then it identifies and explains each type of potential effect by resource and Alternative.

NEPA regulations require a discussion of "any irreversible or irretrievable commitments of resources which would be involved in the proposal should it be implemented" (40 CFR Part 1502.16). An irreversible or irretrievable commitment of resources refers to impacts on or losses to resources that cannot be recovered or reversed. Irreversible is a term that describes the loss of future options where the loss is permanent. It applies primarily to the effects of use of nonrenewable resources, such as minerals or cultural resources, or to those factors, such as soil productivity, that are renewable only over long periods of time. Irretrievable is a term that applies to the loss of production, harvest, or use of natural resources. For example, some or all of the timber production from an area is lost irretrievably while an area is serving as a winter sports site. The timber production lost is irretrievable, but the action is not irreversible; if the use changes, it is possible to resume timber production.

NEPA regulations also require a discussion of "any adverse environmental effects which cannot be avoided should the proposal be implemented" (40 CFR 1502.16). Unavoidable adverse impacts are those that would occur after implementation of any of the Action Alternatives as compared to the No Action Alternative as well as after the implementation of all existing mitigation measures and best management practices. Unavoidable adverse impacts do not include temporary or permanent impacts which would be mitigated. Instead, unavoidable adverse impacts are defined as those that meet the following two criteria:

- There are no reasonably practicable mitigation measures to eliminate the impacts; and
- There are no reasonable alternatives to the proposed project that would meet the purpose and need of the action, eliminate the impact, and not cause other or similar adverse impacts.

Under the Action Alternatives, changes in future coal production are anticipated as a result of changes in the costs of production and associated changes in coal prices. This analysis also considers the potential for coal "stranding" (also referred to as "reserve sterilization"). "Stranding" of coal refers to the situation in which coal that would be economical to mine and technically feasible to mine is made unavailable for extraction as a result of the requirements of the rule. This analysis indicates that there will be no increase in stranded reserves under any of the Alternatives. Under Alternative 2, it is possible that reserves could be stranded in Central Appalachia if disposal capacity is unavailable for excess spoils. No information suggests that adequate disposal capacity would be unavailable; therefore this analysis assumes no stranding of reserves will occur under Alternative 2.

Tables 4.6-1 through 4.6-8 describe the irreversible, irretrievable, and unavoidable adverse environmental effects of the Action Alternatives on each affected resource, as compared to the No Action Alternative. The reader is referred to the appropriate resource-specific section of Chapter 4 for more details in support of the rationale for the findings.

Alternative 2: Irretrievable and unavoidable adverse effects (short-term and long-term) are expected for socioeconomic conditions under Alternative 2. No irreversible, irretrievable, or unavoidable impacts are expected for the following resources–air quality, greenhouse gas emission, and climate change; biological resources; topography, geology, and soils; water resources; land use, utilities, infrastructure, visual resources, and noise; and recreation.

Alternatives 3 through 8: Irretrievable and unavoidable adverse effects (short-term and long-term) are expected for socioeconomic conditions under these Alternatives. No irreversible, irretrievable, or unavoidable impacts are expected for the following resources–air quality, greenhouse gas emission, and climate change; biological resources; topography, geology, and soils; water resources; land use, utilities, infrastructure, visual resources, and noise; public health and safety; and recreation.

Alternative 9: Alternative 9 considers a scenario in which the 2008 Stream Buffer Zone rule is repromulgated and fully implemented across the timeframe of this analysis. Engineering analysis of current coal industry practices finds that, during the period that the 2008 rule was in place, the permits issued in many state programs including those in the Appalachian Basin changed in response to EPA review of Clean Water Act permits such that Alternative 9 would no longer be expected to be functionally different than the No Action Alternative. Alternative 9 is therefore anticipated to have no irreversible, irretrievable, or unavoidable impacts evaluated in this FEIS.

Table 4.6-1. Irreversible and Irretrievable Commitment of Resources and Adverse Environmental Effects under Alternative 2 Compared to the No Action Alternative

Resource	Irreversible	Irretrievable	Unavoidable	Explanation
Air Quality, Greenhouse Gas Emissions, and Climate Change	No	No	No	This Alternative is not expected to result in irreversible or irretrievable commitment of these resources, or in unavoidable adverse effects on these resources. Impacts to these resources are expected to be generally beneficial.
Biological Resources	No	No	No	This Alternative is not expected to result in irreversible or irretrievable commitment of these resources, or in unavoidable adverse effects on these resources. Impacts are anticipated to be beneficial to these resources.
Topography, Geology, and Soils	No	No	No	This Alternative is not expected to result in irreversible or irretrievable commitment of these resources, or in unavoidable adverse effects on these resources. Impacts are anticipated to be beneficial to these resources.
Water Resources	No	No	No	Negligible irreversible or irretrievable impacts for water resources are expected. While the production shift to underground mining in Appalachia could cause some short-term or long-term impacts to groundwater, these are not expected to be irreversible or irretrievable. This Alternative is not expected to result in unavoidable adverse environmental effects on these resources. Impacts are anticipated to be beneficial to these resources.
Land Use, Utilities, Infrastructure, Visual Resources, and Noise	No	No	No	This Alternative is not expected to result in irreversible or irretrievable commitment of these resources, or in unavoidable adverse effects on these resources. Impacts are anticipated to be beneficial to these resources.

Resource	Irreversible	Irretrievable	Unavoidable	Explanation
Socioeconomic Conditions	No	Yes	Short-term and Long-term	Adverse impacts to employment and associated income resulting from decreased coal production represent an irretrievable commitment of socioeconomic resources and an unavoidable adverse effect. Impacts to employment and income may be beneficial in some areas, where benefits to employment from new industry implementation-related work requirements more than offset production-related employment impacts. Adverse impacts to severance tax revenue resulting from decreased coal production represent an irretrievable and unavoidable loss in revenue for local and state governments.
Public Health and Safety	Yes	Yes	Short-term and Long-term	This Alternative is not expected to result in irreversible or irretrievable commitment of these resources, or in unavoidable adverse effects on these resources. Impacts are anticipated to be beneficial to these resources, such as reduced exposure to pollutants in drinking water.
Recreation	No	No	No	This Alternative is not expected to result in irreversible or irretrievable commitment of these resources, or in unavoidable adverse effects on these resources. Impacts are anticipated to be beneficial to these resources.

Table 4.6-2. Irreversible and Irretrievable Commitment of Resources and Adverse Environmental Effects under Alternative 3 Compared to the No Action Alternative

Resource	Irreversible	Irretrievable	Unavoidable	Explanation
Air Quality, Greenhouse Gas Emissions, and Climate Change	No	No	No	This Alternative is not expected to result in irreversible or irretrievable commitment of these resources, or in unavoidable adverse effects on these resources. Impacts to this resource are expected to be beneficial.
Biological Resources	No	No	No	This Alternative is not expected to result in irreversible or irretrievable commitment of these resources, or in unavoidable adverse effects on these resources. Impacts are anticipated to be beneficial to these resources.
Topography, Geology, and Soils	No	No	No	This Alternative is not expected to result in irreversible or irretrievable commitment of these resources, or in unavoidable adverse effects on these resources. Impacts are anticipated to be beneficial to these resources.
Water Resources	No	No	No	Negligible irreversible or irretrievable impacts for water resources to surface water, wetlands or groundwater are expected. Impacts are anticipated to be beneficial to these resources. This Alternative is not expected to result in unavoidable adverse environmental effects on these resources. Impacts are anticipated to be beneficial to these resources.
Land Use, Utilities, Infrastructure, Visual Resources, and Noise	No	No	No	This Alternative is not expected to result in irreversible or irretrievable commitment of these resources, or in unavoidable adverse effects on these resources. Impacts to these resources are expected to be negligible.
Socioeconomic Conditions	No	Yes	Short-term and Long-term	Adverse impacts to employment and associated income resulting from decreased coal production represent an irretrievable commitment of socioeconomic resources and an unavoidable adverse effect. Impacts to employment and income may be beneficial in some areas, where benefits to employment from new industry implementation-related work requirements more than offset production-related employment impacts. Adverse impacts to severance tax revenue resulting from decreased coal production represent an irretrievable and unavoidable loss in revenue for local and state governments.

Resource	Irreversible	Irretrievable	Unavoidable	Explanation
Public Health and Safety	No	No	No	This Alternative is not expected to result in irreversible or irretrievable commitment of these resources, or in unavoidable adverse effects on these resources. Impacts are anticipated to be beneficial to these resources, such as reduced exposure to pollutants in drinking water.
Recreation	No	No	No	This Alternative is not expected to result in irreversible or irretrievable commitment of these resources, or in unavoidable adverse effects on these resources. Impacts are anticipated to be beneficial to these resources.

Table 4.6-3. Irreversible and Irretrievable Commitment of Resources and Adverse Environmental Effects under Alternative 4 Compared to the No Action Alternative

Resource	Irreversible	Irretrievable	Unavoidable	Explanation
Air Quality, Greenhouse Gas Emissions, and Climate Change	No	No	No	This Alternative is not expected to result in irreversible or irretrievable commitment of these resources, or in unavoidable adverse effects on these resources. Impacts to these resources are expected to be beneficial.
Biological Resources	No	No	No	This Alternative is not expected to result in irreversible or irretrievable commitment of these resources, or in unavoidable adverse effects on these resources. Impacts are anticipated to be beneficial to these resources.
Topography, Geology, and Soils	No	No	No	This Alternative is not expected to result in irreversible or irretrievable commitment of these resources, or in unavoidable adverse effects on these resources. Impacts are anticipated to be beneficial to these resources.
Water Resources	No	No	No	Negligible irreversible or irretrievable impacts for water resources are expected. Impacts are anticipated to be beneficial to these resources. This Alternative is not expected to result in unavoidable adverse environmental effects on these resources. Impacts are anticipated to be beneficial to these resources.
Land Use, Utilities, Infrastructure, Visual Resources, and Noise	No	No	No	This Alternative is not expected to result in irreversible or irretrievable commitment of these resources, or in unavoidable adverse effects on these resources. Impacts to these resources are expected to be negligible.
Socioeconomic Conditions	No	Yes	Short-term and Long-term	Adverse impacts to employment and associated income resulting from decreased coal production represent an irretrievable commitment of socioeconomic resources and an unavoidable adverse effect. Impacts to employment and income may be beneficial in some areas, where benefits to employment from new industry implementation-related work requirements more than offset production-related employment impacts. Adverse impacts to severance tax revenue resulting from decreased coal production represent an irretrievable and unavoidable loss in revenue for local and state governments.

Recreation	No	No	No	This Alternative is not expected to result in irreversible or irretrievable commitment of these resources, or in unavoidable adverse effects on these resources. Impacts to these resources are expected to be negligible.

Chapter 5. Consultation and Coordination

5.1 Introduction

To comply with the National Environmental Policy Act (NEPA), Council on Environmental Quality (CEQ), and Department of the Interior regulations implementing NEPA, the Office of Surface Mining Reclamation and Enforcement (OSMRE) has consulted and coordinated with federal and state agencies, organizations, tribes, interested groups, and individuals during the development of the proposed action and both the Draft and Final Environmental Impact Statements (DEIS and FEIS). This chapter provides a summary of the coordination that has occurred up to the publication of this FEIS Public participation and interagency coordination/consultation efforts were ongoing throughout this process to ensure that the best available data is used in developing and analyzing the alternatives developed in this FEIS; and that agency and public concerns and comments are identified, addressed, and incorporated into the planning and decision making process for the Final Rule.

Discussion of the consultation conducted under the ESA section 7(a)(1) is not included in this chapter. Please see the Biological Resources sections of Chapters 3 and 4 for discussion regarding species addressed and of the resulting Biological Opinion. The entire Biological Opinion is available on www.osmre.gov.

5.2 Rulemaking Coordination

Memorandum of Understanding – June 2009

On June 11, 2009, the Department of the Interior entered into a Memorandum of Understanding (MOU) with the Environmental Protection Agency (EPA) and the U.S. Army (representing the U.S. Army Corps of Engineers). The MOU can be viewed on the OSMRE website at: http://www.osmre.gov/resources/mou/ ASCM061109.pdf. The MOU established an Interagency Action Plan (IAP) to reduce the environmental impacts of mountaintop coal mining in the six Appalachian states of Kentucky, Ohio, Pennsylvania, Tennessee, Virginia, and West Virginia. The IAP elements included short term actions to minimize the adverse environmental effects of Appalachian surface coal mining; a commitment to undertake longer term regulatory actions related to Appalachian surface coal mining; coordinated reviews of permit applications under the Clean Water Act (CWA) and the Surface Mining Control and Reclamation Act (SMCRA); and a commitment to engage in robust public participation. The proposed action, the Stream Protection Rule, addresses one objective of the MOU, which was for the signing agencies to consider revisions to key provisions of current SMCRA regulations, including those provisions related to buffer zones around streams and approximate original contour (AOC) requirements.

Advance Notice of Proposed Rulemaking – November 2009

On November 30, 2009, OSMRE published an Advance Notice of Proposed Rulemaking (ANPR) soliciting comments on ten potential rulemaking alternatives (74 FR 62664). OSMRE also invited the public to identify other rules that it should consider revising and announced its intent to prepare an environmental impact statement to supplement the 2008 Stream Buffer Zone Rule EIS. OSMRE received approximately 32,750 comments during the 30-day comment period for the ANPR.

After evaluating the comments, the OSMRE determined that development of a comprehensive stream protection rule was needed, and that the scope of the proposed action required a new environmental impact statement rather than a supplement to the one prepared for the 2008 Stream Buffer Zone Rule.

5.3 Interagency Consultation and Coordination on NEPA Process

OSMRE is the lead agency (see 40 CFR 1508.16) for the NEPA process. In 2010, OSMRE invited all state SMCRA regulatory authorities, tribal governments with an interest in coal lands, and various other state and federal agencies with special expertise or jurisdiction by law to participate in the NEPA process as a cooperating agency (40 CFR 1508.5). Many invitees declined to participate, primarily due to lack of funding and staff or due to other higher priority workload. The U.S. Army Corps of Engineers was one of the federal agencies that declined to participate formally as a cooperating agency. Nevertheless, OSMRE has conducted briefings with the Corps of Engineers to assist in the development of the proposed rule.

The following federal and state agencies accepted invitation to participate as cooperating agencies during the NEPA process:

Federal Agencies:

- U.S. Environmental Protection Agency
- U.S. Fish and Wildlife Service

State SMCRA Regulatory Authorities:

- Utah Division of Oil, Gas and Mining
- New Mexico Mining and Minerals Division
- Kentucky Department for Natural Resources
- Railroad Commission of Texas
- Montana Industrial & Energy Minerals Bureau
- Wyoming Department of Environmental Quality
- West Virginia Department of Environmental Protection
- Alabama Surface Mining Commission
- Indiana Department of Natural Resources
- Virginia Department of Mines, Minerals and Energy
- Ohio Division of Mineral Resources Management

State Historic Preservation Offices:

- Virginia Department of Historic Resources

State Wildlife Agency:

- West Virginia Department of Natural Resources

OSMRE met with the federal cooperating agencies in August 2010 and with several of the state cooperating agencies in September 2010 to discuss the roles of cooperating agencies and development of the DEIS. OSMRE and the cooperating agencies subsequently developed an MOU outlining each agency's role in the NEPA process and identifying specific points of contact within OSMRE and the cooperating agencies.

In late 2010 and early 2011, OSMRE provided all of the cooperating agencies listed above, and the Council on Environmental Quality, the opportunity to review and comment on Chapters 2 through 4 of the first working draft of the DEIS that had been developed by OSMRE's consultant. In October 2010, OSMRE hosted a conference call with the cooperating agencies to discuss their comments on the draft of Chapter 2. A similar conference call was held in January 2011 to discuss comments received on Chapters 3 and 4, with particular emphasis on Chapter 4.

As a result of the preliminary reviews, comments, and coordination with the cooperating agencies through early 2011 that questioned the quality of the analysis and the accuracy of information, OSMRE determined that the preliminary DEIS was insufficient and in need of significant revisions. OSMRE began the revisions to the DEIS in Fall 2011. OSMRE retained the comments received previously from the cooperating agencies and ensured that they were considered during the preparation of the revised DEIS. These comments were very informative as to the scope and content of the analysis needed for the DEIS, including the alternatives, methodologies, and content. The revised DEIS, (published in July 2015) reflects comments and suggestions on the original 2011 preliminary draft, with extensive improvements in the content and analysis over the preliminary draft.

On February 23, 2015, OSMRE received a letter signed by the eleven state regulatory authority cooperating agencies, expressing concern that OSMRE did not provide the cooperating agencies with adequate opportunities to participate in the development of the DEIS since the spring 2011. Further the letter notified OSMRE of the intent of several states to terminate their participation, and several states subsequently did so—Alabama, Kentucky, West Virginia, Utah and New Mexico. Shortly before we announced the availability of the DEIS for public comment, all of the state regulatory authorities except the Wyoming DEQ, voluntarily terminated their role as cooperating agencies.

In a letter dated October 7, 2015, prior to the close of the public comment period on October 26, 2015, we invited the former cooperating state agencies to re-engage as cooperating agencies under NEPA. None accepted this invitation. The Department's Assistant Secretary for Land and Minerals Management, the Director of OSMRE, and other OSMRE officials continued to meet with representatives of states after the close of the comment period, consistent with congressional direction in a report accompanying the Consolidated Appropriations Act of 2016, Pub. L. 114-113. In addition to meetings with state SMCRA regulatory authorities in conjunction with Interstate Mining Compact Commission meetings, the Department of the Interior and OSMRE representatives have either met with or held telephone or video conferences with 14 different state regulatory authorities since the proposed rule was published. We also scheduled meetings for OSMRE and state technical personnel to discuss the scientific studies and other reference documents on two dates (April 14 and 21, 2016). The meetings were held simultaneously in Denver, Colorado; Alton, Illinois; and Pittsburgh, Pennsylvania. Staff from six state regulatory authorities participated in the meeting on April 14, 2016, and staff from five state regulatory authorities participated in the meeting on April 21, 2016.

In a letter dated May 18, 2016, OSMRE provided a set of comments received on the DEIS to the Wyoming DEQ and requested their input on the OSMRE proposed corresponding responses. OSMRE selected the comments sent to the Wyoming DEQ based on their relevance to its specific authority and expertise. The criteria for selection of these comments included whether the comment pertained specifically to resources within the western region or Wyoming and whether the comment pertained to something within the SMCRA oversight responsibilities of the agency. Under these criteria, comments that were more general in nature, for example, on the definition of material damage to the hydrologic balance outside the permit area and how it would be implemented nationwide under any selected alternative, were not included. The selected comments also did not include those received on the proposed rule, or on the Regulatory Impact Analysis, since these comments were addressed separately and these processes were not included within the NEPA cooperating agency relationship. In a return letter dated June 3, 2016, the Wyoming DEQ expressed concern that the comments that OSMRE selected were not inclusive of all the comments provided on the DEIS.. Their letter provided no further input or comments on the proposed corresponding responses provided by OSMRE. In a subsequent letter dated September 30, 2016 OSMRE provided the affected environment chapter of the FEIS to the Wyoming DEQ for review. The Wyoming DEQ responded with comments in a letter dated October 18, 2016; OSMRE made edits where necessary prior to finalizing this FEIS.

In September 2016, OSMRE similarly provided materials associated with the preparation of this FEIS to the non-regulatory authority state cooperating agencies, the West Virginia DNR and Virginia SHPO. Again these materials included comments selected based on the receiving agencies specific authority and expertise and did not include comments and our corresponding responses made on materials other than the DEIS.

OSMRE understands that the state regulatory authorities wanted more input, not only in the DEIS, but also in the rule and the Regulatory Impact Analysis. However, we have sought the input from state regulatory authorities at crucial junctures in the development of the rule—early in the rulemaking process and after publication of the proposed rule. These are the points where the insights of these agencies could best shape the proposal and refine the final rule without impinging on our deliberative process and our ability to craft a rule to meet our purpose and need. Through this extensive outreach, we received input from cooperating agencies and state regulatory authorities at these crucial junctures in the development of the rule. The final version of the preferred alternative has been shaped by this direct input as well as by the information we have gleaned through our oversight of the state programs.

5.4 Tribal Consultation

The Department of the Interior Policy on Consultation with Indian Tribes (DOI, 2011) and OSMRE Directive Reg-18 (OSMRE, 2013), set forth considerations and guidelines for consultation and collaboration between the U.S. government and American Indian and Alaska Natives. Due to the extensive coal reserves on tribal lands, OSMRE invited the Hopi, Navajo, Crow, and Ute Mountain Ute Tribes to be cooperating agencies in the NEPA process; the tribes declined opting instead to provide fulfill their responsibilities in government to government consultation rather than as cooperating agencies under NEPA.

As of this FEIS, we have evaluated the potential effects of this proposed rule on federally-recognized Indian tribes and have determined that its provisions would not have substantial direct effects on the relationship between the federal government and Indian tribes or on the distribution of power and responsibilities between the federal government and Indian tribes. On May 12, 2010, the Director of OSMRE met with the Chairmen of the Hopi and Crow Tribes and the President of the Navajo Nation to initiate consultation on the stream protection rulemaking and development of the DEIS. The tribes in attendance requested that they be kept informed of the rulemaking process and DEIS development. The Director of OSMRE again met with tribal leaders in Washington, DC on December 1, 2011. At that time, OSMRE provided additional information on the elements under consideration for the alternatives in the DEIS and discussed the expected impacts to the SMCRA regulatory program for Indian lands. On August 28, 2015, the Director of OSMRE sent letters to the Hopi Tribe, Crow Tribe, and Navajo Nation notifying them of the publication of our proposed stream protection rule, DEIS and Draft RIA. The letters included an offer to meet with the Tribes and further discuss the proposed rule and DEIS. On November 6, 2015, OSMRE requested government-to-government consultation with the Hopi Tribe, Crow Tribe and Navajo Nation.

At the request of the Navajo Nation, OSMRE Director Pizarchik conducted government-to-government consultation with Tribal leaders in Window Rock, Arizona on January 13, 2016. During the meeting the tribal leaders were briefed on the proposed stream protection rule. Subsequent to that meeting, OSMRE offered to continue government-to-government consultation, on an on-going basis at the request of the tribe. Final consultation occurred on June 15, 2016, during which the tribe indicated they supported a letter previously sent by the Western States and beyond that they had no further comments on the stream protection rule.

OSMRE conducted its final consultation with the Hopi Tribe on June 28, 2016, at which time the Tribal representative indicated that the Hopi Tribe had no further comments on the stream protection rule.

OSMRE also sent letters to the Southern Ute Indian Tribe, Ute Mountain Ute Tribe and Northern Cheyenne Tribe on March 7, 2016 requesting government-to-government consultation on the stream protection rule. The three Tribes did not respond to this request.

OSMRE sent three letters to the Crow Tribe requesting government-to-government consultation on the stream protection rule. These letters were sent in October 2011, August 2015 and November 2015. The Tribe did not respond to these requests. In October 2016 OSMRE made several additional offers to meet for government-to-government consultation but the Tribe did not accept.

5.5 Public Involvement Specific to this NEPA Process

On April 30, 2010, OSMRE published notice of its intent (NOI) to prepare an environmental impact statement to analyze the effects of potential revisions to its rules and regulations under SMCRA to improve the protection of streams from the adverse impacts of surface coal mining operations (75 FR 22723). In this notice, OSMRE set forth eleven principal elements under consideration as part of its revisions to various SMCRA regulations. OSMRE received 25 comments during the 30-day comment period ending June 1, 2010.

On June 18, 2010, OSMRE re-opened the scoping period in order to offer the public additional opportunities to provide comment (75 FR 34666). The reopening allowed an additional 45 days for scoping, which then ended on July 30, 2010. The reopened NOI expanded on the eleven principal elements by including possible alternatives for each element. At that time, the NOI also announced OSMRE's intent to hold public scoping meetings and provided information on how the public could provide comments. OSMRE held nine scoping open houses in coal-producing regions across the U.S.

Scoping Open Houses

Because of the complex nature of the issues for which OSMRE sought input, OSMRE elected to use an open house format for the scoping opportunities rather than a public meeting or public hearing format. OSMRE selected nine cities for the open houses based on their location in or near 95 percent of the coal-producing regions of the U.S. The open houses were held in Beckley, WV; Birmingham, AL; Carbondale, IL; Evansville, IN; Fairfield, TX; Farmington, NM; Gillette, WY; Hazard, KY; and Morgantown, WV between July 19-29, 2010. Open house venues were selected based on estimated interest in the area, facility size, ease of access and parking, availability, and recommendations of the local OSMRE field office.

In addition to the *Federal Register* notice, OSMRE announced the open houses on OSMRE's website (www.osmre.gov) and published display ads in local and regional newspapers for two to four days, two weeks before each open house. The open houses were set up as 12 poster stations that depicted the NEPA process and the eleven principal elements of the proposed action and possible Alternatives, as described in the June NOI. Handouts of the poster, along with a brief introductory explanation, were positioned at each poster station. Comment forms that stated the various mechanisms for submitting comments were made available at each open house. These forms were also set out at each poster station and centrally located to facilitate public participation. OSMRE personnel were available to answer questions and hear attendees concerns. A court reporter was available to take oral comments at all locations, and, in Farmington, NM, a Navajo translator was also available to assist.

Results of Public Scoping

The number of comments received by source is summarized in Table 5.5-1.

Table 5-1. Distribution of Comments Received by Source

Source	Number
Open House – Written	374
Open House – Oral	71
Email at sra-eis@osmre.gov	20,011
Courier or Surface Mail	111
Electronically at www.regulations.gov	4
Total	**20,571**

Most commenters provided specific comments regarding each of the principal elements and possible Alternatives set out in the June 18, 2010 NOI. Some commenters recommended clarifications to existing rules instead of a new rulemaking, made suggestions pertaining to specific elements or Alternatives within the proposed rulemaking, or raised new issues or rule elements for consideration.

Comments were generally divided into two categories: (1) comments in support of rule revisions that would provide greater environmental protection for streams and other natural resources; and (2) comments that support the adequacy of the existing regulations.

Some commenters favoring greater environmental protections advocated interpretation of the 1983 Stream Buffer Zone Rule as an absolute prohibition on stream impacts. This group of comments described the 1983 rules as a bright-line prohibition against any adverse impacts within the stream buffer zone. Other comments suggested that the DEIS assess the effects of an Alternative that would ban surface mining of coal.

Commenters from the Midwest and West also questioned the efficacy of promulgating a nationwide rule when regional differences made many provisions inapplicable or potentially cumbersome, costly, or impractical to apply across the country. They noted that the impetus for OSMRE's action grew from concerns about surface mining operations in the Appalachian region. Table 5.5-2 depicts the numbers of commenters by principal element, as well as by other issues raised.

Table 5.5-2. Distribution of Comments by Principal Element and Other Issues

Principal Element/Other Topics	Number of Comments
Collection of Baseline Data	10,622
Definition of "Material Damage to Hydrologic Balance"	18,628
Mining Activities in or near Streams	10,943
Additional Monitoring Requirements	9,137
Corrective Action Thresholds	583
Landforming and Fill Optimization	10,340
Approximate Original Contour Exceptions	164
Reforestation	304
Financial Assurances for Long-Term Discharges of Pollutants	18,543
Permit Coordination	9,739
Stream Definitions	18,583
NEPA Process	9,114
Justification for Stream Protection Rule (SPR) Lacking	28
Overreaches Statutory Authority	36
Regulations Will Adversely Affect Jobs/Economy/Energy Costs	1,328
Enforcement and Monitoring	18,575
Longwall Mining	5
Additional Research Needed	5
Mining Destroys Cultural Resources	2
Impact of Invasive Species on Ecosystem	3
National Security Concerns	6
Mountaintop Removal Mining Concerns	1

Substantive comments collected during the scoping process were assessed by the NEPA team and incorporated into the scope and content of the DEIS.

Publication of Proposed Rule, DEIS and Draft RIA

On July 16, 2015, we announced that the proposed rule, DEIS, and Draft RIA were available for review at www.regulations.gov, on our website (www.osmre.gov), and at selected OSMRE offices. On July 17, 2015, we published a notice in the *Federal Register* announcing the availability of the DEIS for the proposed rule. See 80 FR 42535-42536. The notice reiterated that the DEIS was available for review at www.regulations.gov, www.osmre.gov, and the OSMRE offices listed in the notice.

The comment period for the DEIS was originally scheduled to close on September 15, 2015. On July 27, 2015, we also published the proposed stream protection rule in the *Federal Register*. See 80 FR 44436-44698. That document reiterated that the proposed rule, DEIS, and draft RIA were available for review at www.regulations.gov, www.osmre.gov, and the OSMRE offices listed in the notice. The comment period for the proposed rule and Draft RIA was also originally scheduled to close on September 25, 2015. In response to requests for additional time to review and prepare comments on all three documents, we extended the comment period for the proposed rule, DEIS, and Draft RIA through October 26, 2015. See 80 FR 54590-54591 (Sept. 10, 2015). Interested parties, therefore, received a total of 102 days to review the proposed rule and supporting documents. During that time, we also held six public hearings in Colorado, Kentucky, Missouri, Pennsylvania, Virginia, and West Virginia. We received approximately 95,000 comments from all sources on the proposed rule, DEIS, and draft RIA.

The comment period we provided fully complies with NEPA as well as the Administrative Procedure Act, 5 U.S.C. 553, which does not set a minimum public comment period for a proposed rule. We also exceeded the 60-day minimum comment period recommended by Section 6(a)(1) of Executive Order 12866 for meaningful public participation. This time is comparable to the comment periods for similar regulations that we have issued in the past. For example, the now-vacated 2008 stream buffer zone rule was subject to a 90-day comment period, while the comment period for the 1978 proposed rule containing most of the original permanent regulatory program regulations was 71 days. It is also noteworthy that many commenters, primarily environmental groups, opposed our 30-day extension of the comment period. They maintained that 60 days was sufficient to review the materials and provide meaningful comment. These and other commenters, including state regulatory authorities, were able to provide extensive, detailed, meaningful comments on the proposed rule, DEIS, and Draft RIA in the comment period provided.

Appendix K of this FEIS provides responses to all comments received during the DEIS comment period. Some topics generated numerous comments that were identical or similar in nature, such that they warranted grouping together. For example, comments on the alternatives we considered or how we calculated certain cost impacts were grouped together. These comments and our responses are contained within Section K.2 of the Appendix, in the Master Responses. Section K.3 provides individual responses to comments.

Chapter 6. Preparers and Contributors

6.1 Introduction

Chapter 6 contains the list of persons involved in the preparation of this Final Environmental Impact Statements (FEIS). The list includes Office of Surface Mining Reclamation and Enforcement (OSMRE) staff and contractors and is found below.

6.2 List of Preparers: Office of Surface Mining Reclamation and Enforcement

Name	Title	Education	Experience
John Ahlbrandt	Surface Mining Reclamation Specialist	B.S. Wildlife Conservation and Management, University of Wyoming	18 years with BLM; 3 years with OSMRE
Arielle Avishai	Physical Scientist, Appalachian Region	B.A. Environmental Studies, GIS, University of Pittsburgh	8 years with OSMRE (GIS and Technology Transfer)
Alex Birchfield	Ecologist, Western Region	B.S. Zoology, magna cum laude; M.S. Restoration Ecology, both from Colorado State University; A.S. Business from Community College of the AF	Over 16 years of experience: 3 years with OSMRE; 8 years with BLM; 5 years with NPS and private consulting
Frank Bartlett	Program Analyst (GIS/Environmental Protection)	B.S. Range Management, Chadron State College; M.S. Range Ecology and Watershed Management, University of Wyoming	2 years with OSMRE; 2 years with Bureau of Land Management
Marcelo Calle	Hydrologist, Western Region	B.S. Watershed Science, Colorado State University	2 years with OSMRE; 6 years with State of Wyoming Abandoned Mine Land and Coal Regulatory Programs
Paul Clark	Hydrogeologist, Western Region	B.A. Geology 1995 Hanover College, M.S. Hydrogeology Wright State University	Panterra Corp, Dayton OH; Tetra Tech EMI, Denver CO; OSMRE
Jeffrey A. Coker	Physical Scientist	B.S. Forest Resource Management, University of Tennessee	25 years with OSMRE; 9 years with the State of Tennessee
Keith Closson	Geographic Information System Specialist, Headquarters	M.A., Geography, The University of Toledo B.A., Psychology, Walsh University	6 years college instructor in geography, 2 years with OSMRE, 1year with Ohio state government in Planning
Debbie Dale	Hydrologist, Mid-Continent Region	B.S. Geology, Nicholls State University; M.S. Geoscience, Univ. of Nevada, Las Vegas	14 years state/federal SMCRA experience; Private environmental consulting

Scott Eggerud	Forester, Appalachian Regional Reforestation Initiative, State and Federal Programs Branch, Appalachian Region	B.S. Forestry and Integrated Natural Resources Univ. of WI - Stevens Point	3 years OSMRE; 22 years WVDEP and WVDOF
Flynn Dickinson	Hydrologist, Indian Program Branch, Program Support Division, OSMRE Western Region	B.S. Landuse Geology, Metropolitan State University of Denver M.S. Environmental Science and Engineering, Colorado School of Mines	5 years with OSMRE
Paul Ehret	Chief, Technical Services Branch, Mid-Continent Region	B.S. and M.S.: Southern Illinois University - Edwardsville	7 years with OSMRE; 29 years with state SMCRA programs in Illinois, Indiana and Kentucky
Robin Ferguson	Environmental Protection Specialist, Headquarters	B.S. Virginia Polytechnic Institute and State University	3 years with OSMRE, 15 years with the Department of the Navy in National Environmental Policy Act work
Kevin Garnett	Mining Engineer P.E.,	B.S. Univ. of Missouri - Rolla	8 years OSMRE Mid-Continent Engineer
Nicholas Grant	Natural Resources Specialist, Mid-Continent Region	B.S. Biology, Southern Illinois Univ. - Edwardsville	6 years with OSMRE Mid-Continent
Thomas Galya	Physical Scientist, Hydrology, Appalachian Region	B.S. West Virginia University, M.S. University of Louisiana, PhD Miami University	11 years with OSMRE; 10 years with WVDEP; 15 years in Industry
Mark Gehlhar	Senior Economist, Headquarters	PhD, Economics, Purdue M.S. Purdue B.S. University of Wisconsin	5 years with OSMRE, 16 with USDA
Dale Herbort	AML Program Specialist	B.A., M.A. Anthropology/Archeology, Kent State University	4 years with OSMRE; 18 years in Montana AML program; 10 years in private consulting
Jeremy Iliff	Anthropologist, Western Region	B.A. Anthropology from Metropolitan State College of Denver 2004.	2 years with OSMRE. Eleven years in the field working for various offices within the USDA Forest Service, Bureau of Land Management and private cultural resource management firms
William Joseph	Chief, Program Support Division, Mid-Continent Region	B.S. Reclamation, University of Wisconsin - Platteville	21 years with OSMRE; 6 years with Kansas Department of Health and Environment
Foster Kirby	Archaeologist, Western Region	B.A. Anthropology Washington State, B.A. & M.A. University of Calgary	30 years with OSMRE
Dave Kovaluk	Visual Information Specialist (Intern)	B.A. Photographic and Electronic Media	2 years with OSMRE Mid-Continent
Brent Means	Hydrologist	M.S. Hydrogeology, Wright State University	13 years with OSMRE; time with USGS and Consulting to Coal Industry

Daniel McKinnon	Natural Resources Specialist, Western Region	B.S. in Biology, Wake Forest University; M.S. in Ecology, Colorado State University	4 years with OSMRE
Amy McGregor	Soil Scientist	B.S. Agronomy-Kansas State University, Secondary Major: Environmental Science -Kansas State University, M.S. Soil Science-University of Idaho	6 years with OSMRE-Denver; 5 years USDA-ARS
Harry Payne	Chief, Regulatory Support Division, Headquarters	A.S. Wildlife Management, Hocking College, Ohio	29 years State of Ohio SMCRA Regulatory Authority; 9 years with OSMRE
Ken Peacock	Natural Resources Specialist	B.S., Michigan State University, M.S. Water Resources, University of Wyoming	20 years with federal government; 5 years with State of Wyoming
George Popper	Geologist, Physical Scientist	B.S., Geology, CCNY M.S., Geology, Univ. Mass. Ph.D., Geology, Lehigh University	College Professor (3 years); Israeli Geologic Survey (2 years); Bendix Field Eng. (5 years); Bureau Mines (2 years); OSMRE (28 years)
Dennis Rice	Regulatory Analyst, Headquarters	V.S., Resources Management (Forestry), State University of New York College of Environmental Science and Forestry	36 years in the regulatory program with OSMRE
Mike Richmond	Civil Engineer	B.S. Civil Engineering, West Virginia Institute of Technology	6 years with OSMRE Charleston Field Office
Kathleen Sheehan	Environmental Protection Specialist	J.D., Duquesne University School of Law B.S. Environmental Studies, University of Pittsburgh	7 years with OSMRE, 10 years' experience total
Cecil Slaughter	Hydrologist	M.S., Water Resources, Iowa State University B.S., Geology, University of Missouri	4 years with OSMRE, 23 years with USGS
Lois Uranowski	Chief, Ecological Services and Technology Transfer Branch	M.S. Civil and Environmental Engineering	24 years engineering experience with OSMRE and private consulting company with hydraulics, geotechnical, mine subsidence & water treatment
Craig Walker	Ecologist	B.S., Forestry; M.S., Ecology, Evolution, and Biology	25 years with OSMRE
William Winters	Chief, Technical Group, Knoxville Field Office	M.S./B.A. Geology, A.S. Business	11 years with OSMRE; 5 years consulting; 6 years state government
Mychal Yellowman	Civil Engineer P.E	B.S. Civil Engineering, Colorado State University	**ears with OSMRE**

6.3 List of Preparers: Industrial Economics, Incorporated (IEc)

Name	Title	Education	Experience
Robert Paterson	Principal Consultant	M.S., Resource Economics and Policy, University of Maine; B.A., Economics, Colby College	19 years
Jason Price	Principal Consultant	M.P.P., University of Michigan; B.A., International Relations, Syracuse University	14 years
Robert Unsworth	Principal Consultant	M.S.F., Yale University; B.S. Forestry, State University of New York	29 years
Rachel Delvecchio	Principal Consultant	M.S. Ocean Engineering, MIT and Woods Hole Oceanographic Institution; B.A. Earth and Environmental Science, Wesleyan	18 years
Leslie Genova	Principal Consultant	M.A. Environmental Studies, Brown University; B.A. Earth and Environmental Science, Wesleyan	15 years
Maura Flight	Senior Associate Consultant	M.S. Economics and B.S. Environmental Science, Rensselaer Polytechnic Institute	14 years
Danielle Mucciarone	Associate Consultant	M.A., Environmental Science and Policy, Clark University; B.S., Environmental Conservation, University of New Hampshire	8 years
Robert Black	Special Consultant	M.S. Public Policy and B.A. Political Science, University of Michigan	27 years
John Weiss	Senior Associate Consultant	M.S. Technology and Policy, Massachusetts Institute of Technology; B.A. Geological Sciences, Brown University	24 years
David Henry	Associate Consultant	M.E.Sc., Yale University; B.A. Mathematics and Economics, Haverford College	5 years
Mary McGee	Senior Research Analyst	B.A. Environmental Economics, Colgate University	2 years

Name	Title	Education	Experience
Jacob Ebersole	Senior Research Analyst	B.A. Economics and Environmental Studies, Dartmouth College	2 years
Gabrielle Carpenter	Research Analyst	B.A. Economics and Environmental Science, Colby College	year

6.4 List of Preparers: RESPEC (Formerly, Morgan Worldwide)

Name	Title	Education	Experience
John Morgan	Principal Consultant	B.Sc. Mining Engineering (Upper Second), Royal School of Mines, University of London	38 years
Garrie Krueger	Senior Mining Engineer	B.S. Mining Engineering, University of Wisconisn-Platteville	18 years
Jack Burchett	Senior Mining Engineer	B.S. Civil Engineering, University of Kentucky	36 years
Nathan Rouse	Mining and Explosives Engineer	Ph.D. Mining/Explosives Engineering and M.S. Explosives Engineering, Missouri University of Science and Technology; B.S. Mining Engineering, University of Missouri Rolla	5 years
Mark Fulhauber	Mining Engineer	M.B.A and B.S. Mining Engineering, University of Kentucky	3 years

6.5 List of Preparers: Energy Ventures Analysis

Name	Title	Education	Experience
Emily Medine	Principal Consultant	M.P.A., Woodrow Wilson School of Public and International Affairs, Princeton University; B.A. Geography, Clark University	28 years
Hans Daniels	Principal Consultant	M.S. Environmental Engineering, University of Colorado, Boulder; B.S. Civil Engineering, Washington University	23 years
Anthony Petruzzo	Associate Consultant	B.S. Business Economics, Miami University	7 years
Aqeel Adenwala	Associate Consultant	M.B.A, Georgetown University; Bachelor of Engineering in Information Technology, Dharmsinh Desai University	5 years

6.6 List of Preparers: Peer Reviewers

Name	Title	Education	Experience
Stephen P. A. Brown	Professor, Economics; Director, Center for Business and Economic Research; Lee Business School, University of Nevada	Ph.D. and M.A. Economics, University of Maryland; B.S. Economics, California Polytechnic State University	36 years
Stephan J. Goetz	Director, Northeast Regional Center for Rural Development; Professor, Agricultural and Regional Economics and Demography; The Pennsylvania State University	Ph.D. and M.Sc. Agricultural Economics, Michigan State University; B.Sc. Agriculture/Agricultural Economics, University of Guelph (Canada).	25 years
John Grubb	Adjunct Professor; Colorado School of Mines	Ph.D. Mining and Earth Systems Engineering, Colorado School of Mines; M.S. Engineering Administration, University of Tennessee; B.S. Mining Engineering, Virginia Polytechnic Institute and State University	39 years
Jack Randall Nawrot	Senior Scientist, Cooperative Wildlife Research Laboratory; Sothern Illinois University	M.A. Zoology, Southern Illinois University; B.A. Biology, Blackburn College	41 years
Raja Ramani	Emeritus Professor, Mining and Geo-Environmental Engineering; The Pennsylvania State University	Ph.D. and M.S. Mining Engineering, The Pennsylvania State University; B.Sc. Mining Engineering, Ranchi University	45 years
W. Douglass Shaw	Professor, Department of Agricultural Economics; Texas A&M University	Ph.D. Economics, University of Colorado; B.A. Geography, University of Colorado	36 years

6.7 Other Contractors

Polu Kai Services, LLC worked on previous drafts of the EIS between June 15, 2010 and February 10, 2011.

Chapter 9. Glossary

Affected Environment: In the context National Environmental Policy Act (NEPA), the environment of the area(s) to be affected or created by the Alternatives under consideration (40 CFR 1502.15).

Allochthonous: Refers to something formed elsewhere rather than its present location.

Alluvial: Pertaining to or composed of alluvium, or deposited by a stream or running water.

Alluvium: A general term for clay, silt, sand, gravel, or other similar material deposited in a streambed, on a flood plain, delta, or at the base of a mountain during comparatively recent geologic time.

Alternative: A combination of management prescriptions applied in specific amounts and locations to achieve a desired management emphasis as expressed in goals and objectives. One of several policies, plans, or projects proposed for decision-making. An Alternative need not substitute for another in all respects.

Alternative, No Action: An Alternative that maintains established trends or management direction.

Anadromous Fish: Fish that are born in fresh water, spend most of their life in the sea, and which return to fresh water to spawn. Common examples include salmon, smelt, shad, striped bass, and sturgeon.

Anaerobic: A situation in which molecular oxygen is virtually absent from the environment.

Angle of repose: Angle between the horizontal and the maximum slope that a particular soil or geologic material assumes through natural processes.

Annual Plants: Plants living for only one growing season and then seeding to form the next generation.

Anthracite Coal: A hard, black lustrous coal containing a high percentage of fixed carbon and a low percentage of volatile matter. Commonly referred to as hard coal, it is mined in the United States, mainly in eastern Pennsylvania, although in small quantities in other states.

Anthropogenic: Of or relating to anthropogenesis; caused by humans.

Anticline: A fold, generally convex upward, whose core contains the stratigraphically older rocks.

Approximate Original Contour (AOC): The surface configuration achieved by backfilling and grading of the mined area so that the reclaimed area, including any terracing or access roads, closely resembles the general surface configuration of the land prior to mining and blends into and complements the drainage pattern of the surrounding terrain, with all highwalls and spoil piles eliminated (SMCRA Section 701(2)). All mined areas are to be returned to AOC, unless they receive a variance from the AOC requirement (SMCRA Sections 515(b) (3) and (c)).

Approximate Original Contour (AOC) Variance: A regulatory authority may grant a variance or waiver from the requirement to restore a site to AOC if certain specified conditions are satisfied.

Aquifer: (a) A layer of geologic material that contains water. (b) A zone, stratum, or group of strata that can store and transmit water in sufficient quantities for a specific use.

Area Mining: Area mining takes place over a ridge or mountainside and is not restricted, as is contour mining, to the side of a mountain. Area mining occurs in locations where lower slopes and the presence of multiple coal seams produce mining ratios that allow for coal extraction across topography rather than around it (as in contour mining). Although area mining may affect a larger area than contour mining, with coal extraction across an entire ridge or mountaintop, it is not considered "mountaintop removal mining", because all the coal seams may not be recovered and the mining area must be restored to AOC.

Augering: A method of mining coal at a cliff or highwall by drilling holes into an exposed coal seam from the highwall and transporting the coal along an auger bit to the surface.

Autochthonous: Formed in its present position.

Backfill: Refilling an excavation. Also, the material placed in an excavation in the process of backfilling.

Badlands: A type of dry terrain where softer sedimentary rocks and clay-rich soils have been extensively eroded by wind and water.

Bank Cubic Yards: The volume of overburden material in the ground before it has been excavated and expanded by swell.

Baseflow: That portion of a stream's discharge that comes from groundwater; ground water seepage into a stream channel.

Bench: Specific to surface mining, this refers to the floor(s) of mining excavation areas where backfilling will occur.

Benthic: Relating to or occurring at the bottom of a body of water.

Best Technology Currently Available: Equipment, devices, systems, methods, or techniques which will (a) prevent, to the extent possible, additional contributions of suspended solids to stream flow or runoff outside the permit area, but in no event result in contributions of suspended solids in excess of requirements set by applicable state or federal laws; and (b) minimize, to the extent possible, disturbances and adverse impacts on fish, wildlife and related environmental values, and achieve enhancement of those resources where practicable. The term includes equipment, devices, systems, methods, or techniques which are currently available anywhere as determined by the Director, even if they are not in routine use. The term includes, but is not limited to, construction practices, siting requirements, vegetative selection and planting requirements, animal stocking requirements, scheduling of activities and design of sedimentation ponds in accordance with 30 CFR parts 816 and 817. Within the constraints of the permanent program, the regulatory authority shall have the discretion to determine the best technology currently available on a case-by-case basis, as authorized by the Act and this chapter (30 CFR 701.5).

Biological Diversity: The relative abundance of wildlife species, plant species, communities, habitats, or habitat features per unit of area.

Biological Opinion: Document stating the U.S. Fish and Wildlife Service (U.S. FWS) and/or the National Marine Fisheries Service opinion as to whether a federal action is likely to jeopardize the continued existence of a threatened or endangered species or result in the destruction or adverse modification of critical habitat.

Bituminous Coal: (1) Coal that ranks between subbituminous coal and anthracite and that contains more than 14 percent volatile matter (on a dry, ash-free basis) and has a calorific value of more than 11,500 Btu/lb. (moist, mineral-matter-free) or more than 10,500 Btu/lb. if agglomerating (American Society for Testing and Materials classification). It is dark brown to black in color and burns with a smoky flame. Bituminous coal is the most abundant rank of coal; much is Carboniferous in age.

Blackwater Stream: Streams that do not carry sediment, are tannic in nature, and which often flow through peat-based areas. Black waters are much more acidic than that of the more neutral waters.

Blanket Drain: Porous zone of large rock formed beneath a valley fill by rolling segregation during wing dumping.

Boreal: Relating to or characteristic of the climatic zone south of the Arctic, esp. the cold temperate region dominated by taiga and forests of birch, poplar, and conifers.

Box Cut: A mining cut excavated into the slope of a hillside, resulting in highwalls on three sides of the cut, or through a mountaintop or ridge crest, resulting in highwalls on two sides of the cut. This type of cut is used to initially open a hillside or mountaintop or ridge crest to all initiation of spoil casting by equipment or explosives.

Bryophyte: Refers to all land plants that do not have true vascular tissue and are therefore also called non-vascular plants.

British Thermal Unit (BTU): A measure of the heat content; the heat required to raise the temperature of one pound of water by one degree Fahrenheit.

Buffer Zone: An area between two different land uses that is intended to resist, absorb, or otherwise preclude developments or intrusions between the two use areas.

Bulking Factor: The net expansion of overburden material resulting from excavation and subsequent backfilling, usually referred to in the mining industry as the swell factor.

Center Ditch: Rock-lined ditch used to carry runoff from the surface of a valley fill down its face to its toe.

Cumulative Hydrologic Impact Assessment (CHIA): Before a Surface Mining Control and Reclamation Act (SMCRA) permit can be approved, an assessment of the cumulative hydrologic impacts of all anticipated mining on the hydrologic balance in the cumulative impact area is performed. Before a SMCRA permit can be approved, the CHIA must find that the proposed operation has been designed to prevent material damage to the hydrologic balance outside the permit area. CHIA preparation is an integrated process which embodies a specific application of hydrologic information management at each step of the process. The scope of a CHIA may initially include all components of the ground water and surface-water systems in the cumulative impact area. This initial scope can be systematically and logically reduced to those concerns of quantity and quality considered significant to maintaining the hydrologic balance of the area. The process focuses on those aspects of the hydrologic balance that are likely to affect designated uses of water. A sample is available at the Office of Surface Mining Reclamation and Enforcement website.

Coal Seam: A layer, vein, or deposit of coal.

Coal Mine Waste: Coal processing waste and underground development waste (30 CFR 701.5).

Coal Processing Waste: Earth materials which are separated and wasted from the product coal during cleaning, concentrating, or other processing or preparation of coal (30 CFR 701.5).

Colluvium: Earth material that has accumulated at the base of a hill, through the action of gravity, as piles of talus, avalanche debris, and sheets of detritus moved by soil creep or frost action.

Confining layer: A layer of earth material that restricts the movement of ground water; material of low hydraulic conductivity.

Coniferous: Of or relating to, or part of, trees or shrubs bearing cones and having evergreen leaves.

Conglomerate: A coarse-grained clastic sedimentary rock, composed of rounded to subangular fragments larger than two millimeters in diameter set in a fine grained matrix of sand or silt, and commonly cemented by calcium carbonate, iron oxide, silica, or hardened clay.

Contour Mining: Surface mining that progresses in a narrow zone following the outcrop of a coal seam in mountainous terrain, and in which the overburden, removed to gain access to the mineral commodity, is immediately placed in the previously mined area, so that reclamation is carried out contemporaneously with extraction.

Core Drain: Central column of porous large rocks in a valley fill formed by rolling segregation and convergence of materials at the valley fill center during wing dumping.

Council on Environmental Quality (CEQ): An advisory council to the President established by the National Environmental Policy Act of 1969. It reviews federal programs for their effort on the environment, conducts environmental studies, and advises the President on environmental matters.

Cover Type: The plant species of a given area, usually described in terms of the dominant species (e.g., oak-hickory, northern hardwood, maple-birch, etc.).

Cross Ridge Mining: Surface mining associated with ridges in steep slope terrain in which the entire coal is extracted by parallel cuts that progress perpendicular to topographic contour and spoil is returned to the mined out area to simulate the approximate premining topography.

Cultural Landscape: A cultural landscape is a geographic area, including both cultural and natural resources and the wildlife and domestic animals therein, associated with a historic event, activity, or person or exhibiting other cultural or aesthetic values. There are four general types of cultural landscapes, not mutually exclusive: historic sites, historic designed landscapes, historic vernacular landscapes, and ethnographic landscapes.

Cultural Resources: For purposes of historic preservation, all of the physical manifestations of archeology and history. Cultural resources include archeological sites, structures and objects significant to American history and prehistory. They may include battlefields, ships, places where treaties were signed, places of significant events. They are important for their representation of cultures, lifestyles, people, architecture, engineering, arts and events, or for the information they contain, or for associations they have with past people or events. Cultural resources are considered fragile and nonrenewable resources, because once they are removed, lost, or destroyed, they are gone forever.

Cumulative Impact: The impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (federal or non-federal) or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time (40 CFR 1508.7).

Cut: An excavation, generally applied to surface mining; to make an incision in a block of coal; in underground mining, that part of the face of coal that has been undercut.

Cyanobacteria: A division of microorganisms that are related to bacteria but are capable of photosynthesis.

Cyclothem: A series of beds deposited during a sedimentary cycle of the type that prevailed during the Pennsylvanian Period. Non-marine sediments often including bituminous coal commonly occur in the lower half of a cyclothem, marine sediments in the upper half.

Deciduous: A tree, shrub, or plant that sheds its leaves annually.

Deltaic: Pertaining to or characterized by a delta.

Demographics: Statistical data characterizing the population of a region and the culture of the people, including such information as age, race, gender, income, education, employment status, etc.

Dendritic: The dendritic drainage pattern is characterized by irregular branching in all directions with the tributaries joining the main stream at all angles. Resembling the vein patterns in a tree leaf.

Detritus: Waste or debris.

Diatom: A major group of algae which are one of the most common types of phytoplankton.

Digital Terrain Model (DTM): A topographic surface or computer representation of terrain stored in a digital data file as a set of three-dimensional (x, y, z) coordinates. The image may be displayed on a computer monitor or portrayed on a map.

Disturbed Area: An area where vegetation, topsoil, or overburden is removed or upon which topsoil, spoil, coal processing waste, underground development waste, or noncoal waste is placed by surface coal mining operations. Those areas are classified as disturbed until reclamation is complete and the performance bond or other assurance of performance is released.

Durable Rock: Naturally formed aggregates that will not slake in water or degrade to soil material. Federal law provides that durable-rock fills must consist of at least 80 percent durable rock (30 CFR 816.73 and 817.73).

Ecological Province: Distinct subdivisions of the landscape containing ecologically related sub-basins. The provinces are distinguished primarily on patterns related to hydrology, climate and regional geology.

Ecohydrological Season: For the purpose of this rule, means a regional specific, annually reoccurring period in which major hydrological and consequent ecological events take place. Specifically in reference to seasonal stream flow, an ecohydrological season is marked by the beginning and end of prolonged periods of presence or absence of flowing water, (i.e. wet and dry seasons) which perpetuate considerable and predictable changes in stream flora and fauna. These periods vary in duration and frequency with respect to region but are always predictable within a typical year.

Effects: Effects include direct effects and indirect effects. Direct effects are caused by the action and occur at the same time and place. Indirect effects are caused by the action and are later in time or farther removed in distance, but are still reasonably foreseeable. Indirect effects may include growth inducing effects and other effects related to induced changes in the pattern of land use, population density or growth rate, and related effects on air and water and other natural systems, including ecosystems. Effect and impacts . . . are synonymous. Effects includes ecological such as the effects on natural resources and on the components, structures and functioning of affected ecosystems, aesthetic, historic, cultural, economic, social or heath, whether direct, indirect, or cumulative. Effects may also include those resulting from actions which may have both beneficial and detrimental effects; even if in balance the agency believes that the effect will be beneficial (40 CFR 1508.8).

Effluent: Partially or completely treated wastewater flowing out of a treatment facility, reservoir, or basin.

Endangered Species: Federally listed endangered species include any species of animal or plant in danger of extinction throughout all or a significant portion of its range; state (group I): species whose prospect of survival or recruitment in the state are in jeopardy in the foreseeable future; state (group II): species whose prospect of survival or recruitment within the state may become jeopardized in the near future.

Endemic Species: Being unique to a particular geographic location, such as a specific island, habitat type, nation or other defined zone. To be endemic to a place or area means that it is found only in that part of the world and nowhere else.

Environmental Assessment (EA): A concise public document prepared to provide sufficient evidence and analysis for determining whether to prepare an Environmental Impact Statement (EIS) or a Finding of No Significant Impact. An EA includes a brief discussion of the need for a proposal, the Alternatives considered, the environmental impacts of the proposed action and Alternatives, and a list of agencies and individuals consulted.

Environmental Impact Statement (EIS): A document prepared to analyze the impacts on the environment of a proposed project or action and released to the public for comment and review. An EIS must meet the requirements of NEPA, CEQ, and the directives of the agency responsible for the proposed project or action.

Ephemeral Stream: A stream which flows only in direct response to precipitation in the immediate watershed or in response to the melting of a cover of snow and ice, and which has a channel bottom that is always above the local water table (30 CFR 701.5).

Epilithic Algae: Algae that grows on rock or stone surfaces.

Escarpment: A cliff or steep slope that separates two level or gently sloping areas. Cliff or steep slope edging higher land.

Eutrophic: Of a lake or other body of water. Rich in nutrients and so supporting a dense plant population, the decomposition of which kills animal life by depriving it of oxygen.

Evapotranspiration: The sum of evaporation and transpiration.

Excess Spoil: (1) Spoil in excess of that necessary to backfill and grade affected areas to the approximate original contour. The term may include box-cut spoil where it has been demonstrated for the duration of the mining operation, that the box-cut spoil is not needed to restore the approximate original contour. (2) Overburden material that is disposed of in a location other than the mine pit (30 CFR 701.5).

Extirpated Species: A species that has become extinct in a given area, although it may exist elsewhere.

Exotic: Those species that occupy habitats in which they did not evolve and in which they often have no natural enemies to limit their reproduction and spread frequently at the expense of native plants and animals and, sometimes, of entire ecosystems. The words exotic, invasive, and non-indigenous are often used synonymously.

Face: The working surface of a coal seam where it is being excavated, usually applied to underground mining. Also, the front of the downstream end of a valley fill.

Factor of Safety: Engineering term expressed in a ratio, used to evaluate slope stability in valley fills with regard to rotational sliding and failure; greater values for a factor of safety indicate greater slope stability.

Fauna: The animals of a particular region or habitat.

Fills: Fill structures that are created by the placement of excess spoil in valleys, on hill sides, or on preexisting benches. Although most excess-spoil fills are commonly referred to as valley fills, most mountaintop-removal and steep-slope mining operations today involve the construction of durable-rock fills (30 CFR Sections 816.71 and 817.71).

Fines: Very fine-grained coal materials or dust typically generated as residue from coal processing facilities.

Flood frequency: Refers to the probability (in percent) that a flood will occur in a given year.

Floodplain: The land adjacent to a stream that is periodically flooded by high water.

Flora: The plants of a particular region or habitat.

Flow Regime: The pattern of stream discharge over time.

Flume: see Core Drain.

Fluvial: Of or pertaining to rivers; produced by the action of a stream or river.

Footwall: The mass of rock beneath a fault, orebody, or mine working; especially the wall rock beneath an inclined vein or fault.

Forb: Any herbaceous plant that is not a grass or grass-like in nature; leafy soft-stemmed plants.

Fragile Lands: Means areas containing natural, ecologic, scientific, or esthetic resources that could be significantly damaged by surface coal mining operations. Examples of fragile lands include valuable habitats for fish or wildlife, critical habitats for endangered or threatened species of animals or plants, uncommon geologic formations, paleontological sites, National Natural Landmarks, areas where mining may result in flooding, environmental corridors containing a concentration of ecologic and esthetic features, and areas of recreational value due to high environmental quality.

Fragipan: A loamy, brittle subsurface horizon low in porosity and content of organic matter and low or moderate in clay but high in silt or very fine sand. A fragipan appears cemented and restricts roots. When dry, it is hard or very hard and has a higher bulk density than the horizon or horizons above. When moist, it tends to rupture suddenly under pressure rather than to deform slowly.

Fugitive Dust: The particulate matter not emitted from a duct or stack that becomes airborne due to the forces of wind or surface coal mining and reclamation operations or both. During surface coal mining and reclamation operations it may include emissions from haul roads; wind erosion of exposed surfaces, storage piles, and spoil piles; reclamation operations; and other activities in which material is either removed, stored, transported, or redistributed.

Geomorphic: Of or relating to the form or shape of the earth.

Geomorphology: The study of landscapes and the processes that change them

Glaciated: Said of an area that is: (1) scoured and worn down by glacial action, or strewn with ice-laid drift; or (2) covered by and subjected to the action of a glacier.

Glacial Deposits: Earth materials deposited as a result of glacial activity.

Glaciation: Alteration of the Earth's solid surface through erosion and deposition by glacier ice.

Glochidium: A parasitic larva of certain freshwater bivalve mollusks, which attaches itself by hooks and suckers to the fins or gills of fish.

Graminoid: Herbaceous plants with narrow leaves growing from the base. They include the "true grasses", of the Poaceae (or Gramineae) family, as well as the grasslike plants such as the sedges (Cyperaceae) and the rushes (Juncaceae).

Groin Ditch: Rock-lined ditch used to carry runoff from slopes surrounding a valley fill to the toe of the valley fill.

Ground Water: Subsurface water that fills available openings in rock or soil materials to the extent that they are considered water saturated.

Hanging Wall: The overlying side of an orebody, fault, or mine working; especially the wall rock above an inclined vein or fault.

Haul Road: (1) A road built to carry heavily loaded trucks at a good speed. The grade is limited on this type of road and usually kept to less than 17 percent of climb in direction of load movement. (2) Road from pit to loading dock, tipple, ramp, or preparation plant used for transporting mined material by truck.

Head (hydraulic): Differential of pressure causing flow in a fluid system, usually expressed in terms of the height of a liquid column that pressure will support. The difference, usually measured in feet, between two water surface elevations; height of water above a specified point.

Head-of-Hollow Fill: A fill structure consisting of any materials, other than a coal processing waste or organic material, placed in the uppermost reaches of a hollow where side slopes of the existing hollow measured at the steepest point are greater than 20 degrees, or the average slope of the profile of the hollow from the toe of the fill to the top of the fill is greater than ten degrees. In fills with less than 250,000 cubic yards of material, associated with steep slope mining, the top surface of the fill will be at the elevation of the coal seam. In all other head-of-hollow fills, the top surface of the fill will be at approximately the same elevation as the adjacent ridge line, and no significant area of natural drainage will occur above the fill, draining into the fill areas.

Headwater: The source (or sources) and upper part of a stream, including the upper drainage basin.

Herbaceous: Term for soft-stemmed grass and forb plant species.

Herpetofauna: A collective term used to describe both amphibians (e.g. frogs, toads, salamanders, newts) and reptiles (e.g. snakes, lizards, turtles).

Higher or Better Uses: Means postmining land uses that have a higher economic value or nonmonetary benefit to the landowner or the community than the premining land uses (30 CFR 701.5).

Historic Property or Historic Resource: Any prehistoric or historic district, site, building, structure, or object included in, or eligible for inclusion in, the National Register of Historic Places. The term "eligible for inclusion in the national Register of Historic Places" includes both properties formally determined as such by the Secretary of the Interior and all other properties that meet the National Register listing criteria.

Highwall: The unexcavated face of exposed overburden and coal or ore in an opencast mine; or the face or bank on the uphill side of a contour strip mine excavation.

Highwall Limits: The maximum economical mining depth for a coal seam as established by its stripping ratio and market value.

Highwall Mining: Removal of coal from beneath a standing highwall without excavation of the overburden, using augers or continuous highwall mining machines.

Historic Lands: Means areas containing historic, cultural, or scientific resources. Examples of historic lands include archeological sites, properties listed on or eligible for listing on a State or National Register of Historic Places, National Historic Landmarks, properties having religious or cultural significance to Native Americans or religious groups, and properties for which historic designation is pending.

Hummock: A general geological term referring to a small knoll or mound above ground. The term hummock, or hummocky, is also applied to extremely irregular surfaces. An earlier use of this term also refers to lumpy terrain; or land that has an irregular shape.

Hydraulic Conductivity: A coefficient of proportionality describing the rate at which water can move through a permeable medium.

Hydric Soil: A soil that is sufficiently wet in the upper part to develop anaerobic conditions during the growing season.

Hydrologic Balance: The relationship between the quality and quantity of water inflow to, water outflow from, and water storage in a hydrologic unit such as a drainage basin, aquifer, soil zone, lake, or reservoir. It encompasses the dynamic relationships among precipitation, runoff, evaporation, and changes in ground and surface-water storage (30 CFR 701.5).

Hydrology: The science that relates to the water systems of the earth, or the principles of water flow, or the presence of surface or ground water.

Hypolimnion: The lower layer of water in a thermally stratified lake, typically cooler than the water above, noncirculating, and thus relatively stagnant and perpetually cold.

Hyporheic Zone: A region beneath and alongside a stream bed, where there is mixing of shallow groundwater and surface water.

Impounding Structure: A dam, embankment or other structure used to impound water, slurry, or other liquid or semi-liquid material (30 CFR 701.5).

Impoundments: All water, sediment, slurry or other liquid or semi-liquid holding structures and depressions, either naturally formed or artificially built (30 CFR 701.5).

Interburden: Rock strata between two coal seams to be mined. Both interburden and overburden are often referred to collectively as overburden.

Interfluve: A region between the valleys of adjacent watercourses, especially in a dissected upland.

Intermittent Stream: (a) A stream or reach of a stream that drains a watershed of at least one square mile, or (b) A stream or reach of a stream that is below the local water table for at least some part of the year, and obtains its flow from both surface runoff and ground-water discharge (30 CFR 701.5).

Invasive: Those species that colonize natural or semi-natural ecosystems, are agents of change, and threats to native biodiversity. The words exotic, invasive, and non-indigenous are often used synonymously.

Karst: A type of topography that is formed over limestone, dolomite, or gypsum by dissolution, and that is characterized by sinkholes, caves, and underground drainage.

Lacustrine: Pertaining to, produced by, or inhabiting a lake or lakes.

Land Use: means specific uses or management-related activities, rather than the vegetation or cover of the land. Land uses may be identified in combination when joint or seasonal uses occur and may include land used for support facilities that are an integral part of the use. Changes of land use from one of the following categories to another shall be considered as a change to an alternative land use which is subject to approval by the regulatory authority.

- Cropland - Land used for the production of adapted crops for harvest, alone or in rotation with grasses and legumes, that include row crops, small grain crops, hay crops, nursery crops, orchard crops, and other similar crops.
- Pastureland or land occasionally cut for hay - Land used primarily for the long-term production of adapted, domesticated forage plants to be grazed by livestock or occasionally cut and cured for livestock feed.
- Grazingland - Land used for grasslands and forest lands where the indigenous vegetation is actively managed for grazing, browsing, or occasional hay production.
- Forestry - Land used or managed for the long-term production of wood, wood fiber, or wood-derived products.
- Residential - Land used for single-and multiple-family housing, mobile home parks, or other residential lodgings.
- Industrial/Commercial - Land used for:
    - Extraction or transformation of materials for fabrication of products, wholesaling of products, or long-term storage of products. This includes all heavy and light manufacturing facilities.
    - Retail or trade of goods or services, including hotels, motels, stores, restaurants, and other commercial establishments.
    - Recreation - Land used for public or private leisure-time activities, including developed recreation facilities such as parks, camps, and amusement areas, as well as areas for less intensive uses such as hiking, canoeing, and other undeveloped recreational uses.
    - Fish and wildlife habitat - Land dedicated wholly or partially to the production, protection, or management of species of fish or wildlife.

- Developed water resources - Land used for storing water for beneficial uses, such as stock ponds, irrigation, fire protection, flood control, and water supply.
- Undeveloped land or no current use or land management - Land that is undeveloped or, if previously developed, land that has been allowed to return naturally to an undeveloped state or has been allowed to return to forest through natural succession (30 CFR 701.5).

Land Reclamation (Mining): The process of creating useful landscapes that meet a variety of goals, typically creating productive ecosystems (or sometimes industrial or municipal land) from mined land. It includes all aspects of this work, including material placement, stabilizing, capping, regrading, placing cover soils, revegetation, and maintenance.

Land Restoration: The process of ecological restoration of a site to a natural landscape and habitat, safe for humans, wildlife, and plant communities.

Lentic: Non-flowing aquatic systems such as ponds.

Lignite Coal: Often referred to as brown coal, this soft brown fuel with characteristics that put it somewhere between sub-bituminous coal and peat. It is considered the lowest rank of coal. In British Thermo Units (BTU's) lignite coal generally ranges between 4,300 to 8,600 BTU's per pound. In the United States, it is mined primarily in the Gulf Coast coal region and in the state of North Dakota in the North Rocky Mountain and Great Plains coal region.

Lithology: The description of rocks, especially in hand section and in outcrop, on the basis of such characteristics as color, mineralogic composition, and grain size.

Littoral Zone: That part of a sea, lake or river that is close to the shore. In coastal environments the littoral zone extends from the high water mark, which is rarely inundated, to shoreline areas that are permanently submerged.

Longwall Mining: A form of underground coal mining where a long wall of coal is mined in a single slice (typically one to two meters thick). The longwall *panel* (the block of coal that is being mined) is typically three to four kilometers long and 250 - 400 meters wide.

Loose Cubic Yards: The volume of overburden material after it has been excavated.

Lotic: Flowing aquatic systems such as streams.

Macroinvertebrate: Animals without backbones, generally visible with the naked eye and associated with freshwater systems. Common examples include insect larvae and crayfish.

Macrophyte: Aquatic plants, growing in or near water that are either emergent, submergent, or floating.

Mesophytic: Being or growing in or adapted to a moderately moist environment.

Mesic: A type of habitat with a moderate or well-balanced supply of moisture.

Metallurgical: Bituminous coal used in a beehive coke oven.

Mine Mouth: The entrance to a mine, or the point of shipping of raw coal from a surface or deep mine operation.

Mineral Extraction Area: Portion of a mine permit where coal will actually be extracted.

Mitigation: Mitigation includes: (a) Avoiding the impact altogether by not taking a certain action or parts of an action. (b) Minimizing impacts by limiting the degree or magnitude of the action and its implementation. (c) Rectifying the impact by repairing, rehabilitating, or restoring the affected environments. (d) Reducing or eliminating the impact over time by preservation and maintenance operations during the life of the action. (e) Compensating for the impact by replacing or providing substitute resources or environments (40 CFR 1508.20).

Morphology: The science of form and structure.

Mountaintop Mining/Valley Fill (MTM/VF) Mining: Surface coal mining occurring on mountaintops, ridges, and other steep slopes (by definition those of 20 degrees or more). Removal of overburden from coal on mountaintop mining sites may result in generation of excess mine spoil in quantities that may not allow regrading of a mine site to its approximate original topographic contours or that must otherwise be disposed of to allow for regrading of a mine site to its approximate original topographic contours or that must otherwise be disposed of to allow for efficient and economical coal extraction. One method of disposing of this excess spoil is to place it the heads of hollows or valleys of streams, a practice often referred to as valley fill. For the purposes of this EIS, steep slope surface coal mining operations that produce excess spoil and dispose of it in heads of hollows or valleys of streams shall be referred to collectively as mountaintop mining/valley fill (MTM/VF) operations, in recognition that repetitive discussion of individual mining methods would be cumbersome.

Mountaintop-Removal Operation: According to SMCRA, a type of surface-mining operation that extracts an entire coal seam or seams running through the upper fraction of a mountain, ridge, or hill. Coal extraction must be accomplished by removing all of the overburden and creating a level plateau or a gently rolling contour that both has no highwalls remaining and is capable of supporting certain postmining land uses.

Mudstone: An indurated mud having the texture and composition of shale but lacking its fissility; a blocky fine-grained sedimentary rock in which the proportions of clay and silt are approximately equal.

Multiple Seam Mining: Surface mining in areas where several seams are recovered from the same hillside.

National Pollutant Discharge Elimination System (NPDES): The national program for issuing, modifying, revoking, and reissuing, terminating, monitoring and enforcing permits, and imposing and enforcing pretreatment requirements, under Sections 307, 402, 318, and 40 of the CWA (40 CFR 122.2).

Nationwide Permits: A type of general permit giving authorization under 33 CFR Part 330 for specified activities nationwide. If certain conditions are met, the activities can take place without the need for an individual or regional permit (33 CFR 325.5(c) (2)).

NeoTropical: Of, relating to, or denoting a zoogeographical region comprising Central and South America, including the tropical southern part of Mexico and the Caribbean.

The National Environmental Policy Act (NEPA) of 1969: Declares the national policy to encourage a productive and enjoyable harmony between man and his environment. Section 102 of that Act directs that "to the fullest extent possible: (1) The policies, regulations, and public laws of the United States shall be interpreted and administered in accordance with the policies set forth in this Act, and (2) all agencies of the federal government shall insure that presently unquantified environmental amenities and values may be given appropriate consideration in decision-making along with economic and technical considerations" (42 U.S.C. §§ 4321-4347; See 33 CFR Part 325, Appendix B).

Noxious Weeds: An invasive species of plant that has been designated by country, state or provincial, or national agricultural authorities as one that is injurious to agricultural and/or horticultural crops, natural habitats and/or ecosystems, and/or humans or livestock.

Oligotrophic: Of a lake or other body of water. Relatively low in plant nutrients and containing abundant oxygen in the deeper parts.

Ordinary High Water Mark: That line on the shore established by the fluctuations of water and indicated by physical characteristics such as clear, natural line impressed on the bank, shelving, changes in the character of soil, destruction of terrestrial vegetation, the presence of litter and debris, or other appropriate means that consider the characteristics of the surrounding areas (33 CFR 328.3(e)).

Outcrop: (a) The part of a rock formation that appears at the surface of the ground. (b) A term used in connection with a vein or lode as an essential part of the definition of apex. It does not necessarily imply the visible presentation of the mineral on the surface of the earth, but includes those deposits that are so near to the surface as to be found easily by digging. (c) The part of a geologic formation or structure that appears at the surface of the earth; also, bedrock that is earth's surface; to crop out.

Outslope: The face of the spoil or embankment sloping downward from the highest elevation to the toe (30 CFR 701.5).

Overburden: Material of any nature, consolidated or unconsolidated, that overlies a coal deposit, excluding topsoil (30 CFR 701.5).

Oviposition: The process of laying eggs by oviparous animals.

Palustrine: Of or pertaining to, or living in, a marsh or swamp; marshy.

Perennial Plants: Plants that live for more than one growing season.

Perennial Stream: A stream or part of a stream that flows continuously during all of the calendar year as a result of ground-water discharge or surface runoff. The term does not include intermittent streams or ephemeral streams.

Periphyton: Freshwater organisms attached to or clinging to plants and other objects projecting above the bottom sediments.

Permeability: The measure of the flow of water through soil. The ease (or measurable rate) with which gasses, liquids, or plant roots penetrate or pass through a layer of soil or porous media. The capacity or ability of a porous rock, sediment, or soil to allow the movement of water through its pores.

Permit: Authorization to conduct surface coal mining and reclamation operations issued by the State Regulatory Authority (SRA) pursuant to a state program or by the Secretary pursuant to a federal program. For purposes of the federal lands program, permit means a permit issued by the SRA under a cooperative agreement or by the Office of Surface Mining Reclamation and Enforcement (OSMRE) where there is no cooperative agreement.

Permit Area: The area of land, indicated on the approved map submitted by the operator with his or her application, required to be covered by the operator's performance bond which includes the area of land upon which the operator proposes to conduct surface coal mining and reclamation operations under the permit, including all disturbed areas; provided that areas adequately bonded under another valid permit may be excluded from the permit area.

Physiographic Province: A region of which all parts are similar in geologic structure and climate and which has had a unified geomorphic history.

Playa: An area of flat, dried-up land; especially a desert basin from which water evaporates quickly.

$PM_{2.5}$: Fine particulate matter which are two and a half micrometers in diameter and smaller.

PM_{10}: Course particulate matter which are smaller than ten micrometers and larger than two and a half micrometers.

Potable Water: Water fit or suited for drinking.

Prime Farmland: Those lands which are defined by the Secretary of Agriculture in 7 CFR part 657 (Federal Register Vol. 4 No. 21) and which have historically been used for cropland (30 CFR 701.5).

Probable Hydrologic Consequences (PHC): A determination of PHC consists of the following steps, repeated as many times as necessary to mitigate adverse impacts: Data collection; Characterization of the premining hydrologic balance; Prediction of mining disturbances; Design of measures to mitigate mining disturbances; and Documentation of residual impacts on the hydrologic balance remaining after implementation of mitigative measures. Any remaining unmitigated impacts must be documented in the PHC determination. The PHC determination process is intended to reduce the predicted adverse impacts on the hydrologic balance to an acceptable level. A sample outline for the PHC determination is available for downloading at the Office of Surface Mining Reclamation and Enforcement website.

Pit: In surface mining, the void left after removal of overburden to expose the coal in a cut.

Plateau: In geology and earth science, also called a high plain or tableland, is an area of highland, usually consisting of relatively flat terrain. A highly eroded plateau is called a dissected plateau. A volcanic plateau is a plateau produced by volcanic activity.

Preparation Plant: A facility where coal is subjected to chemical or physical processing or cleaning, concentrating, or other processing or preparation. A preparation plant's facilities include, but are not limited to, the following: loading facilities; storage and stockpile facilities; sheds, shops, and other buildings; water-treatment and water-storage facilities; settling basins and impoundments; and coal processing and other waste disposal areas.

Production Equipment: Heavy equipment used for primary spoil movement and coal excavation, usually draglines, shovels, hydraulic excavators, or large loaders, the latter three working with haul trucks; also large dozers in the case of cast blasting.

Recharge: In hydrologic terms, rainfall that adds to the residual moisture of the basin in order to help recharge the water deficit (i.e. water absorbed into the soil that does not take the form of direct runoff).

Recovery Rate: The net percentage of the total coal in a reserve that is recovered by mining and not left in the ground. Term can be applied either to the total reserve or to working areas within a reserve.

Reference Area: A land unit maintained under appropriate management for the purpose of measuring vegetation ground cover, productivity and plant species diversity that are produced naturally or by crop production methods approved by the regulatory authority. Reference areas must be representative of geology, soil, slope, and vegetation in the permit area (30 CFR 701.5).

Relief: Difference in elevation between the highest mountaintop, ridge, or hill and the lowest valley within a permit area.

Required Findings: Specific findings that a regulatory authority must make prior to granting a mountaintop-removal or steep-slope AOC variance (Subsections 515(c) and (e) of SMCRA).

Reserve: That portion of the demonstrated coal reserve base that is estimated to be recoverable at the time of determination. The reserve is derived by applying a recovery factor to that component of the identified coal resource designated as the demonstrated reserve base.

Residuum: Material resulting from the decomposition of rocks in place and consisting of the nearly insoluble material left after all the more readily soluble constituents of the rocks have been removed.

Revegetation: Plants or growth that replaces original ground cover following land disturbance.

Rift Zone: A long narrow continental trough bounded by normal faults.

Riparian; Zone, Habitat or Area: Is the interface between land and a river or stream. Riparian is also the proper nomenclature for one of the fifteen terrestrial biomes of the earth. Plant habitats and communities along the river margins and banks are called riparian vegetation, characterized by hydrophilic plants. Riparian zones are significant in ecology, environmental management, and civil engineering because of their role in soil conservation, their habitat biodiversity, and the influence they have on fauna and aquatic ecosystems, including grassland, woodland, wetland or even non-vegetative. In some regions the terms riparian woodland, riparian forest, riparian buffer zone, or riparian strip are used to characterize a riparian zone. The riparian is an important feature of a wetland because it allows characterization of the wetland's overall health.

Room and Pillar: is a mining system in which the mined material is extracted across a horizontal plane while leaving "pillars" of untouched material to support the roof overburden leaving open areas or "rooms" underground. It is usually used for relatively flat-lying deposits, such as those that follow a particular stratum.

Runoff: That portion of the rainfall that is not absorbed by the deep strata, is used by vegetation or lost by evaporation, or that may find its way into streams as surface flow.

Sandstone: A clastic sedimentary rock composed of sand size set in a matrix of silt or clay and more or less firmly untied by a cementing material.

Scope: The range of actions, Alternatives, and impacts to be considered in an environmental impact statement. The scope of an individual statement may depend on its relationships to other statements (40 CFR 1502.20 and 1508.28). To determine the scope of environmental impact statements, agencies shall consider three types of action, three types of Alternatives, and three types of impacts. They include:

- Actions, other than unconnected single actions, which may be: 1) Connected actions, which means that they are closely related and therefore should be discussed in the same impact statement. Actions are connected if they: (i) Automatically trigger other actions which may require environmental impact statements. (ii) Cannot or will not proceed unless other actions are taken previously or simultaneously. (ii) Are interdependent parts of a larger action and depend on the larger action for their justification. 2) Cumulative actions, which when viewed with other proposed actions have cumulatively significant impacts and should therefore be discussed in the same impact statement. 3) Similar actions, which when viewed with other reasonably foreseeable or proposed agency actions, have similarities that provide a basis for evaluating their environmental consequences together, such as common timing or geography. An agency may wish to analyze these actions in the same impact statement. It should do so when the best way to assess adequately the combined impacts of similar actions or reasonable alternatives to such actions is to treat them in a single impact statement.

- Alternatives, which include: 1) "No Action" Alternative. 2) Other reasonable courses of actions. 3) Mitigation measures (not in the proposed action).

- Impacts, which may be: 1) Direct; 2) Indirect; 3) Cumulative (40 CFR 1508.25).

Sediment: Solid material, both mineral and organic, that is in suspension, is being transported, or has been moved from its site of origin by air, water, gravity, or ice and has come to rest on the earth's surface either above or below sea level.

Sediment Channel/Ditch: See Perimeter Ditch.

Sedimentary Rock: A layered rock resulting from the consolidation of sediment. Examples of such rocks include shale, siltstone, limestone, and sandstone.

Sedimentation: The process of depositing sediments carried by water.

Sedimentation Pond: A reservoir for the confinement and retention of silt, gravel, rock, or other debris from a sediment-producing area.

Severance Tax: A tax levied against coal as it is mined, based either on the value of the coal or at a flat rate per ton, used to compensate federal, state, and sometimes local governments for the value of the portion of the reserve that is extracted.

Shrinkage Factor: Percent decrease in loose material volume resulting from backfilling and subsequent compression by overlying material.

Significantly: "Significantly" as used in NEPA requires consideration of both context and intensity:

- Context - This means that the significance of an action must be analyzed in several contexts, such as society as a whole (human, national), the affected region, the affected interests, and the locality. Significance varies with the setting of the proposed action. For instance, in the case of a site-specific action, significance would usually depend upon the effects in the locale rather than in the world as a whole. Both short- and long-term effects are relevant.

- Intensity - This refers to the severity of impact. Responsible officials must bear in mind that more than one agency may make decisions about partial aspects of a major action. The following should be considered in evaluating intensity:

    - Impacts that may be both beneficial and adverse. A significant effect may exit even if the federal agency believes that on balance the effect will be beneficial.

    - The degree to which the proposed action affects public health or safety.

    - Unique characteristics of the geographic area such as proximity to historic or cultural resources, park lands, prime farmlands, wetlands, and wild and scenic rivers, or ecologically critical areas.

    - The degree to which the effects on the quality of the human environment are likely to be highly controversial.

    - The degree to which the possible effects on the human environment are highly uncertain or involve unique or unknown risks.

    - The degree to which the action may establish a precedent for future actions with significant effects or represents a decision in principle about a future consideration.

    - Whether the action is related to other actions with individually insignificant but cumulatively significant impacts. Significance exists if it is reasonable to anticipate a cumulatively significant impact on the environment. Significance cannot be avoided by terming an action temporary or by breaking it down into small component parts.

    - The degree to which the action may adversely affect districts, sites, highways, structures, or objects listed in or eligible for the listing in the National Register of Historic Places, or may cause loss or destruction of significant scientific, cultural, or historic resources.

    - The degree to which the action may adversely affect an endangered or threatened species or its habitat that has been determined to be critical under the Endangered Species Act of 1973.

- Whether the action threatens a violation of federal, state, or local law or requirements imposed for the protection of the environment (40 CFR 1508.27).

Siltstone: An indurated silt having the texture and composition of shale but lacking its fine laminations or fissility.

Sinuosity (of a stream): The degree of curvature of a stream.

Slake Durability: The ability of rock or spoil materials to resist dissolution or breakdown in water; used for assessing the suitability of spoil material for use in valley fill construction.

Socioeconomic: Relating to social and economic factors of a population or geographic region, such as income, industry structure, employment, health, and general well-being.

Soil: The unconsolidated mineral or organic material on the immediate surface of the earth that serves as a natural medium for the growth of land plants. (ii) The unconsolidated mineral or organic matter on the surface of the earth that has been subjected to and shows effects of genetic and environmental factors of: climate (including water and temperature effects), and macro- and microorganisms, conditioned by relief, acting on parent material over a period of time. A product-soil differs from the material from which it is derived in many physical, chemical, biological, and morphological properties and characteristics. Please refer to the Natural Resources Conservation Service website (http://soils.usda.gov/) for more detailed information regarding a specific soil taxa or regime.

Soil Horizons: Contrasting layers of soil parallel or nearly parallel to the land surface. Soil horizons are differentiated on the basis of field characteristics and laboratory data. The four master soil horizons are:

- A horizon - The uppermost mineral layer, often called the surface soil, is the part of the soil in which organic matter is most abundant, and leaching of soluble or suspended particles is typically the greatest;

- E horizon - The layer is commonly near the surface below an A horizon and above a B horizon. An E horizon is most commonly differentiated from an overlying A horizon by lighter color and generally has measurably less organic matter than the A horizon. An E horizon is most commonly differentiated from an underlying B horizon in the same sequum by color or higher value or lower chroma, by coarser texture, or by a combination of these properties;

- B horizon - The layer that typically is immediately beneath the E horizon and often called the subsoil. This middle layer commonly contains more clay, iron, or aluminum than the A, E, or C horizons; and

- C horizon - The deepest layer of soil profile consists of loose material or weathered rock that is relatively unaffected by biologic activity.

Special Handling: General term for methods of blending, isolation, or encapsulation of toxic materials within the backfill to prevent adverse impacts to chemical water quality.

Species Richness: The number of different species in a given area.

Spoil Bank: An accumulation of overburden. Also, underground mine refuse piled outside.

State Program: A program established by a state and approved by the Secretary pursuant to Section 503 of the Act to regulate surface coal mining and reclamation operations on non-Indian and non-federal lands within that State, according to the requirements of the Act and this chapter. If a cooperative agreement under part 745 has been entered into, a state program may apply to federal lands, in accordance with the terms of the cooperative agreement (30 CFR 701.5).

Steep Slope: Any slope of more than 20 degrees or such lesser slope as may be designated by the regulatory authority after consideration of soil, climate, and other characteristics of a region or state (30 CFR 701.5).

Steep-Slope Mining: Type of surface-mining operation where the natural slope of the land within the proposed permit area exceeds an average of 20 degrees.

Storage Capacity: The amount of water that can be store in a specific volume of rock.

Stratigraphic Classification: The arrangement of the sequence of rock strata of the earth's crust into units with reference to the many different characteristics, properties, or attributes which the strata possess.

Stratigraphy: Geology that deals with the origin, composition, distribution, and succession of strata. Study or description of layered or stratified rocks.

Stratum: Geologic term for a sedimentary rock bed, plural strata.

Stripping Ratio: The unit amount of spoil or overburden that must be removed to gain access to a unit amount of coal. It is generally expressed in cubic yards of overburden to raw tons of mineral material.

Sub-Bituminous Coal: Coal of rank intermediate between lignite and bituminous. In the specifications adopted jointly by the American Society for Testing and Materials (D388-38) and the American Standards Association (M20.1-1938), subbituminous coals are those with calorific values in the range 8,300 to 13,000 Btu's calculated on a moist, mineral-mater-free basis, which are both weathering and non-agglomerating according to criteria in the classification.

Support Areas: Portions of a mine permit that are maintained to support the production and development areas, such as haul roads, building facilities, and erosion and sedimentation control facilities.

Substrate: The material that composes the bed or bottom of a stream or lake.

Swale: A low place in a tract of land. A wide, shallow ditch, usually grassed or paved. A wide open drain with a low center line.

Swell: The tendency of soils and bedrock, on being removed from their natural, compacted beds, to increase or swell owing to the creation of voids or spaces between soil or rock particles. The volumetric increase, normally expressed as a percentage that occurs as the consequence of changing undisturbed overburden (bank) into loose (excavated) material.

Swell Factor: The percentage increase in the volume of rock material as it is broken to form spoil, resulting from the creation of voids between the broken rock fragments that were not present in the original unbroken rock. Also used in industry as the equivalent to the term “bulking factor,” or the net percentage increase between the volume of rock material and its resultant spoil after compaction in backfill.

Syncline: A fold in rocks in which the strata dip inward from both sides towards the axis.

Tableland: A broad, high, level region; a plateau.

Taxonomy: The science of categorization, or classification, of things based on a predetermined system.

Terrace: A level or nearly level plain, generally narrow in comparison with its length, from which the surface slopes upward on one side and downward on the other side. Terraces and their bounding slopes are formed in a variety of ways, some being aggradational and others degradational.

Threatened Waters: Waters rated by the states as "threatened" currently support all of their designated uses, but one or more of those uses may become impaired in the future (i.e., water quality may be exhibiting a deteriorating trend) if pollution control actions are not taken.

Thrust Fault: A fault with a dip of 45 degrees or less over much of its extent, on which the hanging wall appears to have moved upward relative to the footwall.

Topography: The general configuration of a land surface, including its relief and the position of its natural and man-made features.

Topsoil: The A, O, and E soil horizon layers of the four master soil horizons.

Toxic Material: Specific to coal mining, this includes overburden strata or coal materials that have been identified as containing materials that may result in adverse impacts to chemical water quality if exposed to air and water.

Transmissivity: The ability of an aquifer to transmit water.

Transpiration: The process by which plants give off water vapor through their leaves.

Underground Mining: Also known as deep mining, a process by which coal is extracted by excavating within the horizon of a coal seam and without removing the overlying overburden for reasons other than primary seam access.

Valid Existing Rights: Means a set of circumstances under which a person may, subject to regulatory authority approval, conduct surface coal mining operations on lands where 30 U.S.C. §§ 1272(e) and 761.11 would otherwise prohibit such operations.

Valley Fill: A fill structure consisting of any material other than coal waste and organic material that is placed in a valley where side slopes of the existing valley measured at the deepest point are greater than 20 degrees, or the average slope of the profile of the valley from the toe of the fill to the top of the fill is greater than ten degrees.

Vascular Plant: Also known as tracheophytes or higher plants. Those plants that have lignified tissues for conducting water, minerals, and photosynthetic products through the plant. Vascular plants include the clubmosses, *Equisetum*, ferns, gymnosperms (including conifers) and angiosperms (flowering plants).

Vector Data: A data model based on the representation of geographical object by Cartesian coordinates, commonly used to represent linear features. Each feature is represented by a series of coordinates which define its shape, and which can have linked information.

Waters of the United States: Those waters included in this term pursuant to 33 CFR Part 328. For purposes of this EIS, OSMRE assumes that this term includes: intrastate lakes, rivers, streams (including intermittent streams), mudflats, sandflats, wetlands, sloughs, prairie potholes, wet meadows, playa lakes, or natural ponds Final authority regarding determinations as to the status of waters as "waters of the United States" pursuant to the Clean Water Act remains with the U.S. Environmental Protection Agency.

Watershed: An area drained by a single river or river system, defined by a ridgeline

Wetland: Those areas that are inundated or saturated by surface or ground water at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions (Section 404 of the Clean Water Act). For resource mapping purposes, the U.S. FWS (Cowardin et al., 1979) has also defined wetlands as follows: Lands transitional between terrestrial and aquatic systems where the water table is usually at or near the surface or the land is covered by shallow water. For purposes of this classification, wetlands must have one or more of the following three attributes: (1) At least periodically, the land supports predominantly hydrophytes; (2) The substrate is predominantly undrained hydric soils; and (3) The substrate is non-soil and is saturated with water or covered by shallow water at some time during the growing season of each year.

Wing Dumping: End dumping of spoil from haul trucks on opposite sides of a valley fill area to create blanket and core drains beneath the fill.

Xeric: Of an environment or habitat containing little moisture; very dry.

Zero-Order Stream: Swales and hollows that lack distinct stream banks but serve as conduits of water, sediment, nutrients, and other materials during rainstorms and snowmelt.

Appendices

Appendix A. Common Coal Mine Effluent Standards (NPDES, 40 CFR 434)[1]

40 CFR Part 434 governs coal mine discharges and is broken into various sub-categories. Each category has four types of effluent standards based on the industry's ability to treat the associated effluent and the age of the facility.

Best Practicable Control Technology Currently Available (BPT): Effluent limitations guidelines representing the degree of effluent reduction attainable by the application of the best practicable control technology currently available.

Best Available Technology Economically Achievable (BAT): Effluent limitations guidelines representing the degree of effluent reduction attainable by application of the best available technology economically achievable.

Best Conventional Pollutant Control Technology (BCT): Effluent limitations guidelines representing the degree of effluent reduction attainable by the application of the best conventional pollutant control technology.

New Source Performance Standards (NSPS): Technology-based standards for facilities that qualify as new sources under 40 CFR 122.2 and 40 CFR 122.29. Standards consider that the new source facility has an opportunity to design operations to more effectively control pollutant discharges.

Table A-1.
BPT standards for coal preparation plants and associated areas all with effluent pH < 6.0 S. U. prior to treatment, and acid or ferruginous mine drainage from active mining areas including underground mines until the Surface Mining Control and Reclamation Act of 1977 (SMCRA) bond release

Pollutant or Pollutant Property	Maximum for any 1 day (mg/l)	Average of Daily Values for 30 Consecutive Days (mg/l)
Iron, total	7.0	3.5
Manganese, total	4.0	2.0
Total Suspended Solids (TSS)	70	35
pH	6 to 9 S. U. at all times	6 to 9 S. U. at all times

S. U. = Standard Units

Discharges from reclaimed areas	SS, pH			pH

Appendix B. Biological Assessment of Streams[2]

B.1 Introduction

Streams have long been used as a measuring stick to determine ecological health. Reasons behind this choice are due to the intimate connection streams have with wildlife, the landscape, and their role within surface and ground water systems. Aquatic bioassessments evaluate the condition of a water body using biological surveys and other direct measurements to the resident biota (Gibson et al., 1996). Bio-monitoring is the systematic use of biological responses to evaluate changes in the environment with the intent to use this information in a quality control program (Rosenberg and Resh, 1993). Stream bioassessments and biomonitoring programs are used throughout the world to evaluate and monitor stream health as well as degradation and/or recovery in response to disturbance. The most common group of organisms used for biological assessment is macroinvertebrates; however, assessment methods are available which incorporate fish and algae as well (Barbour et al., 1999).

B.2 Stream Bioassessment Methods

Throughout the U.S. streams have been given varying degrees of protection from direct and indirect impacts. Impacts can be temporary, such as non-permanent structures (e.g., access roads or sediment ponds that will be reclaimed) or these impacts can be permanent (e.g., significant stream subsidence, stream fills, or stream relocations). The mining of coal can impact streams both directly and indirectly. Mining can contribute indirectly by producing off-site impacts to streams via chemical contamination and directly by producing significant changes to the physical attributes of streams (Barbour et al., 1996; Pond et al., 2008).

Section 303(c) of the Clean Water Act (CWA) outlines the water quality standards program which includes the states' requirement to protect biological integrity. To accomplish this, many states have used the guidance and methods outlined in the U.S. Environmental Protection Agency's (EPA) Rapid Bioassessment Protocol (RBP) (Barbour et al., 1999) for their biological assessment program. The updated RBP is designed to be quick, affordable, understandable, and adaptable to regional differences in the physical and biological structure of streams. The RBP contains single habitat (riffle/run) and multihabitat approaches to sampling which includes surveys of stream biology (e.g., taxa richness, identification of sensitive and tolerant species, number of individuals, critical habitat elements, and observed pathologies) for the biological assessment of aquatic resource quality (Barbour et al., 1999; Gerritsen et al., 2000). Many states have also established numeric biocriteria defining a score that represents the expected biological community of a reference stream. The biocriteria that are used in these assessments are typically based on metrics.

[2] This information is provided as background information in support of the discussions contained within the FEIS. Corrections have been made where necessary in response to comments on the DEIS, however OSMRE has not updated this information since publication of the DEIS.

Metrics allow the investigator to use indicator attributes to assess the status of assemblages or communities in response to impacts. Each metric is a characteristic of the organism(s) that changes in a predictable way to disturbance. These relate to the abundance and types of aquatic organisms found in the streams, and the connections between certain groups of organisms.

Individual metrics are often combined to produce multi-metric indices (MMIs), which are single numerical characterizations of communities. MMIs combine metrics from different categories and are sensitive to a wider range of pollution and environmental stressors. MMIs can provide a more accurate indication of biological integrity than individual metrics by capturing a wider range of elements and processes. Metrics and MMIs are further described below.

B.2.1 Biocriteria

The fish, insects, algae, aquatic plants and other biota in a waterbody provide effective information about the condition of that waterbody because the aquatic biota is continuously exposed to the various stressors present (e.g., water quality, clarity, and temperature). Chemical measurements alone only provide information on the condition at the time of sampling, and cannot assess the mid- and long-term effects of habitat degradation. Biological information not only reflects current status but also provides a relevant way to evaluate changes in conditions over time and can help assess cumulative impacts (Barbour et al., 1999). Therefore, biological assessments have become common supplementary information to chemical and physical assessments of water quality.

Biocriteria provide benchmark measurements that describe the desired condition of a system and can serve as a direct comparison of the condition of the biota that lives in the observed aquatic systems to the desired condition. Biological assessment indices are developed as an aggregation of individual metrics that are the most informative and relevant to the ecology of the streams within the area of study or are the most sensitive to a particular stressor of interest. Numeric biocriteria scores may be used depending upon the region, and what questions are being asked within the assessment (Barbour et al., 1999).

Under the CWA, biocriteria are defined as numerical values or narrative statements that define a desired biological condition for a waterbody and are part of the water quality standards. Most state biocriteria were developed according to EPA guidance in the RBP.

According to the RBP, biocriteria development:

- Is developed using data collection at a range of reference sites (which represent the natural range of variation in "minimally" disturbed water chemistry, habitat, and biological conditions) and non-reference (or "test") sites;
- Uses the classification of streams based on physical, chemical and biological attributes;
- Develops appropriate metrics (indictors) that best discriminate between reference and streams with identified anthropogenic stressors. Candidate metrics should be the most informative and relevant to the ecology of the streams within the ecoregion; and
- Establishes a threshold to differentiate between impaired and non-impaired streams (Barbour et al., 1999).

B.2.2 Metrics

Biocriteria are developed based on biological metrics, which generally fall into five categories; taxa richness, relative abundance, tolerance/intolerance, feeding group, and habit. The most valuable metrics are those that respond predictably to the environmental stressor(s) of interest. When developing biocriteria for stream monitoring programs most states have selected metrics that respond best to general perturbation or anthropogenic disturbance. However, metrics which respond well to specific stressors are also used to more closely examine and monitor a particular impact.

Taxa richness is the number of unique taxa in a standard sample and is a measure of diversity. High levels of diversity suggest that niche space, habitat, and food sources are adequate to support a diverse biological community (Barbour et al., 1999). Examples of taxa richness metrics include total species richness and the number of species found within the insect orders Ephemeroptera, Plecoptera, and Trichoptera (EPT), i.e., the number of mayfly, stonefly, and caddisfly species.

Relative abundance (or composition) metrics provide information on the relative contribution of the various taxa to the total community. For example, the dominance of pollution tolerant taxa (e.g., high value for the Percent Chiromidae metric), suggests stream impairment (Barbour et al., 1999). Other examples of relative abundance metrics include Percent Top Dominant Species and Percent Ephemeroptera.

Tolerance/intolerance metrics are intended to represent the sensitivity of the biological assemblage to disturbance and/or different stressors. Measurements include numbers of pollution tolerant and intolerant taxa and/or their percent abundance. Examples of tolerance metrics include percent intolerant taxa and the Hilsenhoff Biotic Index (HBI). The HBI is based on categorizing macroinvertebrates depending on their response to organic pollution. Macroinvertebrates have an assigned pollution tolerance value ranging from zero to ten (ten being the most tolerant reading). The HBI is calculated as the total sum of the number of specimens in each taxonomic group (n_i) multiplied by its pollution tolerance score (a_i), divided by the total number of organisms in the sample (N): $HBI = \Sigma\, ni\, ai/N$. Although the HBI is calibrated for organic pollution, by adjusting tolerance values it may be adapted to examine biological responses to other stressors such as elevated conductivity and sedimentation (Hilsenhoff, 1987).

Feeding group measures (or trophic dynamic metrics) provide information on the balance of feeding strategies and mechanisms that a macroinvertebrate uses to acquire food (Merritt and Cummins, 1996). Scrapers (e.g., scraping algae from hard surfaces), shredders (e.g., feeding on leaf litter falling into a stream), collectors (e.g., filter feeders and collectors), and predators (e.g., hunters) are common feeding strategies in benthic environments. Stressors that cause instability in food dynamics will cause an alteration in the composition of functional feeding groups from the least disturbed or reference condition (Barbour et al., 1999).

Metrics related to habit (or modes of existence) evaluate the composition of morphological adaptations that allow organisms to attach, move, and/or conceal themselves in their environment (Merritt and Cummins, 1996). Changes in habit metrics can indicate changes in available habitat niches. For example, an increase in the Percent Herptobenthos (i.e., organisms adapted to living in soft substrates such as sand or mud) metric and decrease in Percent Haptobenthos (i.e., organisms adapted to living on hard substrates such as cobble) metric is an expected response to a stream receiving increasing inputs of excessive sedimentation.

A list of commonly used macroinvertebrate metrics is provided in Table B-1 below.

Table B-1.
Commonly Used Macroinvertebrate Metrics

Category	Metric	Explanation	Expected Response to Perturbation
Richness Measures	Taxa Richness	Number of macroinvertebrate families	-
	EPT Index	Number of mayfly (Ephemeroptera), stonefly (Plecoperta), and caddisfly (Trichoptera) families	-
	Number of Ephemeroptera (mayfly) Taxa	Number of mayfly families	-
Abundance Measures	Percent EPT	Percent abundance of mayfly nymphs, stonefly nymphs, and caddisfly larvae and pupae.	-
	Percent Dominant Taxon	Percent abundance of the single most abundant taxon	+
	Percent Five Dominant Taxa	Percent abundance of the five most abundant taxa combined	+
	Percent Chironomidae	Percent abundance of larvae and pupae in the non-biting midge family Chironomidae	+
	Simpson Diversity Index	Integrates richness and evenness into a measure of general diversity $\lambda = 1 - \sum_{k=1}^{S} P_k^2$ Where: S = number of taxa P_k = proportion of individuals in taxa k	-
	HBI (Hilsenhoff Biotic Index)	Weighted sum of the total taxa by pollution tolerance $HBI = \sum \frac{x_i t_i}{n}$ Where: x_i = number of individuals within a taxon t_i = tolerance value of a taxon n = total number of organisms in the sample	+
Tolerance Measures	Percent Intolerant	Percent abundance of macroinvertebrates with tolerance values of three or less	-
	Percent Tolerant	Percent abundance of macroinvertebrates with tolerance values of seven or higher	+
	Number of Intolerant Taxa	Number of macroinvertebrate families, genera, species, or combination of these, with tolerance values of three or less	-
	Number of Tolerant Taxa	Number of macroinvertebrate families, genera, species, or combination of these, with tolerance values of seven or higher	+

Habitat Measures	Percent Haptobenthos	Percent abundance of macroinvertebrates requiring clean, coarse, firm substrates (assigned habitat of clinger or crawler).	-
	Percent Herptobenthos	Percent abundance of macroinvertebrates adapted to living in or on fine, soft substrate or substrate covered with thick, slippery films of algae, bacteria, or fungi (assigned habitat of sprawler or burrower).	+
Trophic (feeding group) Measures	Percent Scrapers	Percent abundance of macroinvertebrates scraping and feeding upon periphyton	-

B.2.3 Development of Multi-metric Indices and Bioassessment Protocols

Metrics can be reviewed either independently or as multi-metric indices (MMIs). Several state water quality programs have developed numeric biocriteria and threshold standards for impairment based on a MMI calibrated and verified for their region(s). Examples of state MMIs include the West Virginia's Stream Condition Index (WVSCI) and Ohio's Invertebrate Community Index (OHICI) (Gerritsen et al., 2000; WVDEP, 2010; OHEPA, 1989; OHEPA, 2013).

Though the details differ, most state water quality programs use calibrated MMIs to establish biocriteria and meet the requirements of the CWA to monitor and protect the biological integrity of its waters. Calibrated indices require strict adherence to designated protocol. Deviating from a specified bioassessment protocol can impact the results greatly and invalidate the resulting data. Accurate application of an index is typically limited by both a specific sampling season and a specific region (e.g., state, ecoregion, or watershed). Adhering to the correct collection method is also important. The WVSCI protocol requires semi-quantitative sampling of riffle habitat using a dip net. In comparison, the OHICI uses quantitative sampling by collecting macroinvertebrates via Hester-Dendy multiple-plate artificial substrate samplers submerged in the run of a target stream for minimum of six weeks (Gerritsen et al., 2000; WVDEP, 2010; OHEPA, 1989; OHEPA, 2013).

Most state CWA Section 303(c) biomonitoring programs use regional reference sites to establish biocriteria for their state's streams. Regional reference data are collected from a population of relatively unimpaired sites within a relatively homogeneous region. The advantages of using regional reference sites for biomonitoring include: broad comparability and extrapolation of measurements; use of a large dataset provides an accurate estimate of variance; and once established, the reference sites should not require continuous sampling. However, establishment of a regional reference standard requires a substantial short-term effort and the measurements may prove too broad to adequately address specific questions about the biological integrity of a particular location. Many state programs and independent researchers often supplement regional reference data with a site-specific reference. A site-specific reference is typically a location upstream of a pollution point source or a nearby "paired" watershed that is not subjected to the point source. If properly selected, the general ecology (minus the source of impairment) of the two sites should be nearly identical, thereby strengthening conclusions about cause and effect. However, the data collected is very site specific and requires continuous sampling of the reference location(s). Additionally, studies employing site-specific reference locations typically have few replicates, so estimates of variance may prove less accurate than necessary (Barbour et al., 1999).

The required sample size and taxonomic precision (i.e., family vs. genus level assessments) varies widely between protocols. Many protocols may use subsampling methods to achieve a roughly standardized sample size and/or assist with making the field collected samples smaller and more manageable for sorting and identification. The WVSCI requires a subsample of 200 individuals identified to family level taxonomy. In comparison, the OHICI protocol requires identification of the entire field collected sample (i.e., no subsampling) to genus level taxonomy. Identification to family level requires less time, less training, is less prone to misidentifications, and produces data with lower variance often making statistical analyses more revealing. Genus level identification requires specialized training, additional equipment, and more time, but provides increased sensitivity to detecting impaired biological conditions and the causes of impairment (Pond et al., 2008; Bailey et al., 2001).

Each MMI is composed of several individual metrics from several categories standardized into a single score designed to represent the condition of the sampled stream community. For example, the WVSCI is composed of six family-level macroinvertebrate metrics from four categories (i.e., Total Taxa, EPT Taxa, Percent EPT, Percent Chironomidae, Percent Top Two Dominant Taxa, and HBI). These six metrics were chosen from a selection of 24 candidate metrics based on their efficiency to discern between known reference sites and known impaired sites. Each metric is converted to a standardized score of 0 (most impacted) to 100 (least impacted). The six scores are then averaged to commute a final single multi-metric index score. Scores greater than 78 are considered highly comparable to reference streams whereas a score of 68 has been established as the threshold for impairment. However, to allow the highest degree of confidence a threshold of 60.6 is used for the purposes of identifying biological impairment within West Virginia's 303(d) list (Gerritsen et al., 2000; WVDEP, 2010).

Bioassessment and biomonitoring methods provide a holistic approach to gauge and monitor the conditions of a stream. A stream's biological community reflects the ecological integrity of the stream and its surrounding watershed. Biological communities integrate the effects of multiple stressors to provide an aggregate measurement of their impact. When properly used, biomonitoring methods can assist stream restoration and reconstruction projects by insuring the re-establishment of the stream's ecological integrity (i.e., the chemical, physical, and biological integrity).

Appendix C. Aquatic Systems In Coal Mining Regions[3]

C.1 Lotic (Flowing) Aquatic Systems

Lotic or flowing aquatic systems are common landscape features in areas where coal mining is conducted. Lotic systems include creeks, springs, streams, rivers, etc. This section will discuss the various lotic systems and their features and functions within the study area. The descriptions provided here in this section are based on the generally accepted physical and ecological characteristics that define these systems; these definitions will not necessarily be identical to the regulatory definitions used in SMCRA the CWA or elsewhere.

C.1.1 Physical Characteristics

Various physical factors such as stream gradient, light, precipitation, flow volume, substrate, and water chemistry influence the biota of lotic systems (Allan and Castillo, 2007). These physical factors are determined by relief of the landscape, climate, lithology, elevation, and land use in the area within a particular segment of stream.

C.1.2 Stream Classification

Stream ordering has been a traditional method of classifying streams (Strahler, 1957). This classification system uses the size and position of a stream within a drainage network to assign a particular order. A first-order stream does not have tributaries. A confluence of two streams of the same order promotes the system to the next stream order. For example, the union of two first-order streams produces a second-order stream; a joining of two second-order streams creates a third-order stream, and so on. There is no formal definition of a *headwater stream*, but it is often referred as a first- to third-order stream that occurs at the top of a watershed (e.g., U.S. EPA et al., 2003; Levick et al., 2008). Many headwater streams do not show up on 1:24,000 topographic maps published by the U.S. Geological Survey. Cartographers have difficulty seeing and interpreting the character of small streams on aerial photos, especially in forested areas. In addition, cartographers have used different methods and relied on aerial photos of varying quality to determine these first and second order streams. (Colson, et al, 2008). Headwater streams may be perennial, intermittent, or ephemeral (Nadeau and Rains, 2007; Levick et al., 2008).

C.1.3 Ephemeral and Intermittent Streams

A generally accepted way to define an ephemeral stream is as stream or reach of a stream that flows only during and shortly after discrete precipitation events or in response to the melting of snow and ice. The

[3] This information is provided as background information in support of the discussions contained within the FEIS. Corrections have been made where necessary in response to comments on the DEIS, however OSMRE has not updated this information since publication of the DEIS.

channel bottom is always above the local water table; thus, groundwater is not a source of streamflow in an ephemeral stream. An ephemeral stream typically lacks the biological, hydrological, and physical characteristics commonly associated with the continuous or seasonal conveyance of water; organisms with very short or aestivating aquatic life stages may be present.

Intermittent streams and intermittent stream reaches are below the local water table for part of the year and obtains theirs flow from both surface runoff and groundwater discharge. An intermittent stream possesses the biological, hydrological, and physical characteristics commonly associated with the seasonal conveyance of water. The biological communities of intermittent streams include species that are aquatic during a part of their life cycle, are capable of diapauses or other dormancy periods, or move to perennial water sources in dry conditions.

Often, ephemeral and intermittent streams serve as the headwaters and tributaries for many higher-order streams, but their location and the amount of flow that occurs within them varies among precipitation events (Levick et al., 2008). In addition, ephemeral streams have poorly developed banks or lack them, whereas intermittent streams tend to have moderately developed banks. Literature that discusses the ecological functions of ephemeral and intermittent streams is limited but state that ephemeral and intermittent streams move water, nutrients, sediment, and debris downstream, collect and store water, and provide connectivity within watersheds (Levick et al., 2008; Bernhardt and Palmer, 2011). Ephemeral and intermittent streams also provide habitat for a variety of flora and fauna (Molles, 2005). Many organisms found in ephemeral and intermittent streams live in the streambed substrate, even when surface water is not running (Boulton et al., 1998).

Levick et al. (2008) discussed the functions of ephemeral and intermittent streams:

> Ephemeral and intermittent streams are responsible for a large portion of basin ground-water recharge in arid and semi-arid regions through channel infiltration and transmission losses. These stream systems contribute to the biogeochemical functions of the watershed by storing, cycling, transforming, and transporting elements and compounds. Ephemeral and intermittent streams support a wide diversity of plant species, and serve as seed banks for these species. Because vegetation is more dense than in surrounding uplands, ephemeral and intermittent streams provide habitat, migration pathways, stop-over places, breeding locations, nesting sites, food, cover, water, and resting areas for mammals, birds, invertebrates, fish, reptiles and amphibians. In arid and semi-arid regions, the variability of the hydrological regime is the key determinant of both plant community structure in time and space and the types of plants and wildlife present.

C.1.4 Perennial Streams

A perennial stream is a stream or reach of a stream that flows continuously during the entire calendar year as a result of groundwater discharge or surface runoff. A perennial stream exhibits biological, hydrological, and physical characteristics commonly associated with the continuous conveyance of water. The biological communities of perennial streams support aquatic organisms year-round and may support major fisheries. The term does not include any stream or reach of a stream that meets the definition of an intermittent stream or an ephemeral stream. Perennial streams maintain continuous flow by groundwater discharge (baseflow) to the streambed. Flow in first- and second-order perennial streams is relatively low compared to higher order perennial streams. The starting points of perennial streams may fluctuate due to annual precipitation fluctuations. In years with drought, seemingly perennial reaches of a stream can be separated by ephemeral or intermittent segments of flow because of differences in geographic composition along the stream.

C.1.5 Higher-order Streams/Rivers

Higher-order streams tend to be perennial streams classified as fourth-order and above. The U.S. Environmental Protection Agency (EPA) describes fourth-order streams to sixth-order streams as mid-sized, and seventh-order streams and above as larger streams or rivers (U.S. EPA et al., 2003). Nevertheless, higher order streams perform the same critical hydrologic functions as lower order streams: they move water, sediment, nutrients, and debris and provide connectivity within the watershed (Levick et al., 2008).

C.1.6 Habitats in Streams

One of the most influential factors determining the habitat and biota of streams is stream gradient. Stream velocity is directly controlled by gradient and discharge, which also, in part, influences: the types of substrate that occur on the streambed; dissolved oxygen levels in water; and water and terrestrial temperatures. Streams can be divided vertically into three zones: the surface, the water column, and the benthic zone (Molles, 2005). The benthic zone includes the bottom substrates and the depths at which a significant amount of surface water still flows, i.e. the river bed. Below the benthic zone, a transitional area between surface water flow and groundwater flow exists; this is called the hyporheic zone. The area below the hyporheic zone where groundwater flows is called the phreatic zone; during periods of no visible streamflow, interstitial water flows through the material below the stream into the hyporheic zone (U.S. EPA et al., 2003; Molles, 2005). Levic et al. 2003 states, "during hyporheic flow, stream water and groundwater mix in the beds and banks of ephemeral, intermittent, and perennial streams and sometimes in regions surrounding stream channels."

The interstitial spaces among sediment particles in the hyporheic zones of streams are occupied by a diverse array of aquatic invertebrates including crustaceans, flatworms, rotifers, aquatic mites, and larval and juvenile stages of insects (Boulton et al., 1998). Stream alluvium is often looser than the soils or the colluvium of surrounding uplands, which enhances the potential for exploitation by specialized burrowing species (Levick et al., 2008). For example, some macroinvertebrates burrow into the hyporheic zone to continue their life cycles during times of drought (U.S. EPA et al., 2003). Boulton et al. (1998) noted that species of surface invertebrates have been documented to use the hyporheic zone as refugia from floods, droughts, predation, and deterioration of water quality. Some macroinvertebrates are specialized to live solely within the hyporheic zones of streams (Hynes, 1970). Biofilms that accumulate organisms and organic materials on the surface of bottom-substrates are an important source of food for the organisms in the hyporheic zones. Hyporheic organisms also are important in that they break down detritus trapped in the sediment and serve as important links in the food chain (Boulton et al., 1998).

In hyporheic zones, there is substantial biogeochemical cycling of nutrients and trace elements that are essential to aquatic life (Valett et al., 1994; Boulton et al., 1998; Hibbs, 2008; Levick et al., 2008). Boulton et al. (1998) noted that in streams where the flowing water exchanges with the hypoheic zone, nutrient exchange between the zones can promote high levels of productivity. Upwelling of water in desert streams can promote algal growth, thus promoting the uptake of nitrogen (Grimm, 1987).

Ephemeral and intermittent stream channels provide important habitat because they commonly have a higher moisture content and more abundant vegetation than the surrounding areas. In some areas, these streams may have perennial segments or permanent pools, thus retaining the only available water within a catchment area (Levick et al., 2008). These isolated perennial waters can support life not found in an otherwise ephemeral system.

Streams can be divided into the following general characteristics: pools, riffles, runs, and rapids. Pools are depositional areas where flow is slow or stagnant, allowing finer particulate matter to settle onto the stream bottom. Riffles often occur in higher gradient habitats where relatively shallow surface water flows over coarser substrate, creating turbulence within the water column and disturbance on the surface of the water. This increases levels of dissolved oxygen by encouraging the mixing of oxygen in the air with the flowing water. Runs are moderately fast sections of streams where the water surface is not as turbulent as riffles. Rapids are characterized by steep gradients, high water velocity, and turbulence over substrate resistant to erosion. Headwater streams typically consist of alternating riffles and runs; small depositional pools may be present and represent an important microhabitat. Mid-sized and larger rivers typically contain all four features because increased width, depth, and length allow for more variation in flow.

Overhanging vegetation, submerged and floating leaf packs, in-stream vegetation, large woody debris, undercut banks, and exposed tree roots all contribute to the habitat diversity for macroinvertebrates, amphibians, reptiles, mammals, and fish (U.S. EPA et al., 2003; Allan and Castillo, 2007). Levick et al. (2008) noted that ephemeral and intermittent stream channels provide important wildlife movement corridors in arid and semi-arid regions because they contain continuous chains of vegetation that wildlife can use for cover and food. Stream bank and buffer zone material provides shelter for numerous species of wildlife, including reptiles, amphibians, birds, mammals and invertebrates (Levick et al., 2008). Stream features such as littoral areas (zones close to the shore where light may penetrate to the streambed) provide cover and nursery habitat for macroinvertebrates and fish, as well as provide feeding areas for wildlife; these features exist most prominently in depositional systems such as larger-order rivers (U.S. EPA et al., 2003).

Wetlands and riparian zones are transitions between terrestrial and aquatic habitats, and occur along streams and lentic systems (U.S. EPA et al., 2003). Wetlands and riparian zones are used by some stream biota during periods of elevated flow. The Army Corps of Engineers (USACE, 1987) define wetlands as:

> Areas that are inundated or saturated by surface or groundwater at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions.

Riparian wetlands can typically be found on floodplains along higher order streams. Typical steep geomorphology of headwater streams usually prohibits the formation of a floodplain, so wetlands are usually restricted to small depression areas (U.S. EPA et al., 2003). As stream gradient decreases, the presence of wetlands usually increases. Wetlands associated with streams are forested wetlands, emergent marshes, wet meadows, and small ponds; they all function as habitat for aquatic flora and fauna and other terrestrial wildlife. The unique characteristics and vegetative composition of wetlands provide habitat for a variety of organisms, including amphibians, migratory birds, and smaller organisms such as macroinvertebrates.

C.1.7 Ecological Functions

The ecological functioning of streams is interconnected to the land immediately adjacent to the stream—the riparian buffer zone. Riparian buffer zones provide a number of functions including: sediment control from upland areas; stream-bank stabilization; nutrient addition and extraction; wildlife habitat; temperature moderation; and flood control.

C.1.7.1 Sediment Control from Upland Areas

Natural and anthropogenic erosion from upland areas contributes to sediment in surface water runoff. Generally, as this runoff passes through the riparian buffer zone, increased friction with vegetation and organic litter slows its velocity, thereby allowing increased water infiltration into the soil, larger sediment particles to settle, and an increase in the adhesion of finer clay-like particles to the riparian vegetation and litter. The efficacy to trap sediment is dependent upon many factors, including the: size distribution of incoming sediments; water depth relative to vegetation height; vegetation type; slope; width; and flow characteristics. A more detailed discussion of these factors follows.

As the velocity of runoff entering a riparian buffer zone slows, coarse particles falling from suspension are deposited in the first few feet of the riparian zone, so long as sheet flow is maintained and channelization is avoided. Finer particles are carried further into the riparian zone. While rapid deposition is beneficial in the short term, it may ultimately render the riparian buffer zone ineffective if the sediment buries the riparian vegetation or if a natural barrier forms at the upland area-riparian zone interface. In these situations, channelized flow, as opposed to sheet wash flow, would likely occur and would considerably reduce the efficiency to trap sediment. A riparian buffer zone of a sufficient width is necessary to slow the water velocity enough to allow fine sediment deposition.

More sediment is deposited in the riparian buffer zone when water depths are lower than the height of the riparian buffer zone vegetation. For example, a study of the Black Creek in Indiana found that when surface water flow was lower than grass height, as much as 54 percent reduction in sediment loads were recorded, but when vegetation is clipped to below the surface water level, filtering efficiency ultimately declines to zero (Karr and Schlosser, 1978). In other studies, the interaction between groundwater level and vegetation height seemed to be more complex, with vegetation height, soil type, and type of sediment being significant factors of sediment filtration from shallow flow (e.g., Pearce et al., 1998).

Natural forest buffers are also effective in removing sediments, but, in general when comparing riparian buffer zones of same width, grass filters (and other dense herbaceous vegetation) are more effective in sediment removal than woody vegetation (Neibling and Alberts, 1979; Young et al., 1980; Osborne and Kovacic, 1993; Parsons et al., 1994; Gilliam et al., 1997). Still, the efficiency of forested buffers to control sediment is high. Cooper et al. (1987) found a forested buffer removed 84 to 90 percent of the sediment from cropland runoff. Also, Lowrance et al. (1995) reported similar trapping efficiencies (80 to 90 percent) in forested buffer zones in a Coastal Plain.

Efficiency in trapping sediments is generally greater on gentle slopes than steeper slopes (Karr and Schlosser, 1978; Peterjohn and Correll, 1984; Jordan et al., 1993; and Dillaha and Inamdar, 1997). Steeper topography promotes greater velocities of overland flow, increasing the ability of the flow to transport higher concentrations of sediment and reducing water infiltration time into the ground. Gentle slopes generally have more uniform cover characteristics than steeper slopes, and consequently overland flow on steeper slopes tends to concentrate and form cannels whereas gentle slopes tend to create sheet flow. These factors may contribute to less sediment trapping efficiency on steeper slopes. Some researchers believe that certain slopes are too steep to be effective sediment traps; however, there is no consensus on this critical angle, which is thought to generally range from ten to 40 percent (McNaught et al., 2003). After an extensive review of the literature, Wenger (1999) suggested that the critical angle for an effective buffer was 25 percent.

Early research by the EPA on environmental protection in surface coal mining (Grim and Hill, 1974) suggested a minimum riparian buffer zone width of 100 feet to efficiently trap most of the sediment from an upland area, although the researchers conceded that the required width varies with steepness and length of the outslope between the toe and the drainage channel. More recently, researchers for the Chesapeake Bay Program suggested that as long as sheet wash flow is maintained, a buffer width of 50 to 100 feet is adequate for the removal of sediment (Palone and Todd, 1998). Peterjohn and Correll (1984) studied the effectiveness of a 164-foot riparian zone with a five percent slope in the Mid-Atlantic Coastal Plain and found 94 percent efficiency in sediment removal but also found 90 percent of the sediment was removed in the first 62 feet. Based on research in the 1950s by the U.S. Forest Service in the White Mountains in New Hampshire (Trimble and Sartz, 1957), a simple formula, which included adjustment for slope, was developed as a means to establish a sediment buffer between forest roads and streams:

25 feet + 2.0 feet (slope percent).

Work by Swift (1986) in Nantahala National Forest in North Carolina suggested that slope distance should be adjusted using the following formula:

43 feet + 1.39 feet (slope percent).

Swift also suggested that if a brush barrier was present the formula should be further adjusted to the following:

32 feet + 0.40 feet (slope percent).

After a review of numerous studies and recognizing that vegetated buffer zones as narrow as 15 feet were found to efficiently trap sediment, Wenger (1999) stated that a 100 foot buffer zone is generally adequate for the removal of sediment.

Buffers are most effective when uniform sheet flow through the buffer zone is maintained. Dillaha et al. (1988) studied the efficiency of orchardgrass (*Dactylis glomerata*) plots for controlling sediment and nutrients from feedlots on slopes of 11 to 16 percent. They found that in plots with uniform sheet flow, 81 to 91 percent of sediment and soluble solids were effectively trapped, but the efficiency was much less where concentrated (channel) flow occurred. Channelization of surface runoff is a natural process and has a tendency to occur with increased precipitation, reduced infiltration, lack of or reduced ground cover, increased slope, and distance. Once flow becomes channelized, the ability to trap sediment is significantly reduced (Karr and Schlosser, 1978; Dillaha et al., 1989; Osborne and Kovacic, 1993; Daniels and Gilliam, 1996).

Channelized flow reduces the efficiency of vegetation and litter to slow the runoff velocity to promote suspended particles to settle. It also reduces the time for surface flow to infiltrate into the buffer zone, hindering the filtering of very fine particles. Daniels and Gilliam (1996) reported that ephemeral channels are ineffective sediment traps during high-flow. Lowrance et al. (1995) concluded that buffer zones are most effective in trapping sediment in ephemeral and headwater streams because there is a greater proportion of surface runoff that enters the buffer zone as shallow sheet wash.

C.1.7.2 Stream Bank Stabilization

Another potential source of sediment is from the stream bank. A study by Grissinger et al. (1991) found that more than 80 percent of the total sediment yield for a stream in northern Mississippi originates from channel erosion. Rabeni and Smale (1995), Cooper et al. (1993), and Lowrance et al. (1985) also found that stream channels can be a significant source of sediment.

One of the most important roles of riparian buffer zones is to stabilize stream banks. Beeson and Doyle (1995) found that non-vegetated banks were more than 30 times as likely to suffer severe erosion as fully vegetated banks. Barling and Moore (1994) note that buffers can prevent the formation of rills and gullies in riparian areas that are otherwise highly susceptible to erosion. Vegetation in the riparian area exerts a strong control over the condition and stability of the stream and its banks (Palone and Todd, 1998). In the eastern U.S. trees often define the physical characteristics of stream channels. Trees anchor stream bank soils through dense root masses, and large roots provide physical resistance to water flow. Woody debris anchors channel substrate and determines bar formation, stores large amounts of streambed sediment and gravel, helps control sinuosity, and provides channel structure through pool/riffle or step formation. Until recently, the value of large woody debris was misunderstood and much was removed throughout the country. It is likely that the direct effect of buffer width on this function is limited. Only vegetation within 25 feet of the stream channel would provide a powerful role in stabilization. However, increasing buffer width would indirectly enhance stream stability by providing additional protection during extreme flood events, channel migration, and as a physical barrier to human impact (Palone and Todd, 1998).

To be effective, bank vegetation should have a good, deep root structure which holds soil (Wenger, 1999). Shields et al. (1995) tested different configurations of vegetation and structural controls in stabilizing banks. They found that native woody species, especially willow, are best adapted to re-colonizing and stabilizing banks. Wenger (1999) noted that the persistent exotic vine kudzu is likely the most serious barrier to vegetation restoration because it can out-compete native vegetation, although kudzu can provide some stabilization via its root structure. Artificial methods of stream bank stabilization, such as applying riprap or encasing the channel in cement, are effective in reducing bank erosion on site but could increase erosion downstream and have negative impacts on other stream functions. Artificially stabilized banks lack the habitat benefits of forested banks and are expensive to build and maintain (Wenger, 1999).

Relatively narrow vegetative buffers are effective in the short term (USACE, 1991). As long as banks are stabilized and damaging activities are kept away from the channel, width of the riparian buffer zone would not appear as a major factor in preventing bank erosion. However, it is important to recognize that some erosion is inevitable and stream channels would migrate laterally; therefore, a buffer zone wide enough to permit channel migration is recommended (Wenger, 1999).

C.1.7.3 Nutrient Removal

Riparian buffer zones may also perform the function of removing nutrients, such as nitrates and phosphates, which would otherwise enter streams, rivers, and lakes. Excessive nutrient loads imbalance natural aquatic systems and can produce algal blooms and conditions with little or no oxygen dissolved in the water, leading to fish kills. Removing nutrients is especially important on mine reclamation, agricultural lands, and urban settings where fertilizer is used. In addition, the buffer zones may also help reduce sulfate (Correll and Weller, 1989; Jordan et al., 1993), which is often associated as a pollutant when coal or overburden contains pyrite.

Nutrients may be in suspension or dissolved in water. In suspension, nutrients are often affixed to sediment. As previously discussed, riparian buffer zones are effective in reducing the amount of particulate matter that enters a stream, so these same processes would apply when speaking about the amelioration of nutrients. In a dissolved form, nutrients enter the buffer zone in surface water and/or groundwater. Riparian buffer zones effectively remove nutrients in the dissolved form, but there is no consensus on which mechanisms are most responsible. The mechanisms most often mentioned include: denitrification (microbial reduction of nitrate to nitrogen gas); assimilation and retention by the vegetation; and transformation to ammonium and organic nitrogen followed by retention in the soils of the riparian buffer zones. Few studies have accurately measured the amount of nitrate removed by any of these mechanisms at a given site and no study has measured the removal rate by all of three mechanisms (Correll, 1997). Denitrification is most often invoked as the primary mechanism of nitrate removal; however, the extreme spatial and temporal variability of denitrification rates in riparian buffer zones make it very difficult to determine accurate fluxes (Correll, 1991; Weller et al., 1994). Phosphates are not effectively removed by this process because of the lack of an analogous microbial activity (Lowrance et al., 1997).

Some studies conclude that assimilation by the vegetation is the primary mechanism of nitrate removal (e.g., Fail et al., 1986); this mechanism would also account for the uptake of phosphorus. Studies have shown that the total amount of nitrogen in the biomass only accounts for 30 percent of the nitrate removal (Peterjohn and Correll, 1984; Correll and Weller, 1989). Correll (1997) suggests that the assimilation by vegetation and recycling to the forest floor as litter is important in unraveling the primary mechanism of nitrate removal. This flux of organic nitrogen delivered to the forest floor as litter could be gradually mineralized and denitrified at the soil surface. While vegetation may be very important in explaining nutrient removal within the riparian buffer zone, nutrient removal continues in the winter at sites where hardwood deciduous forests are dormant (Correll, 1997).

Some scientists believe that nitrate removal is accomplished by chemical rather than biological denitrification (Mariotti et al., 1988). The below ground conditions in riparian buffer zones are often anaerobic or of low oxidation/reduction potential (Eh) for portions of the year. The below-ground processes that result in this low Eh are composed of a series of biogeochemical reactions that occur in a defined order (Billen, 1976). These reactions transfer electrons from organic matter, released from the plants, to various terminal electron acceptors. The availability of terminal electron acceptors determines which level in the series would dominate below-ground processes at any one time and place in the riparian zone. Some of the more commonly important reactions are manganate ion reduction, denitrification, ferric iron reduction, sulfate reduction, and methanogenesis. None of these reactions can take place in the presence of molecular oxygen. Despite the relative ease of measuring soil Eh, few studies have reported this critical parameter (Correll, 1997).

Nutrients, especially phosphorus, are likely in solid form and are subjected to the same processes and limitations as other suspended solids. The long-term efficacy of riparian buffer zones to trap phosphorus is highly questionable. Whereas nitrate can be denitrified and released to the atmosphere, phosphorus is taken up by vegetation, adsorbed into the soil or organic matter, precipitated with metals, or released into the stream or groundwater (Lowrance, 1998).

The effectiveness of the riparian buffer zone to trap dissolved nutrients is highly dependent on the hydrology, soils, and vegetation. To illustrate, the volume and pathway of the groundwater passing through the riparian buffer zone would influence its ability to effectively retain nutrients. If the local groundwater passes beneath the riparian buffer zone or the whole system is at too great a depth, the riparian zone and groundwater cannot interact to trap nutrients (Correll, 1997). In diverse topography, in gentle slope areas and broad alluvial floodplains, the depth of groundwater is near the surface where nutrient trapping can be accomplished, but, in steep terrain, the water table in the riparian zone typically is much deeper. In the latter case, the interaction between the saturated zone and the root zone is quite small (Lowrance et al., 1995).

Along with hydrology, soil characteristics are important in determining the potential for removal of nitrogen and pollutants (e.g., phosphorus, pesticides) carried by sediment. Primary considerations are soil texture, depth to water table, microbial activity, and organic matter content. Moderate- to well-drained soils have the greatest permeability and intercept large amounts of water that may enter the buffer zone as surface flow, thus promoting deposition of sediment and related pollutants. Conversely, moderate- to fine-textured soils have superior potential to create conditions favorable for extensive denitrification (Palone and Todd, 1998). Soil microorganisms have the capacity to process nitrate at high concentrations. Riparian buffer zones support a variety of microbial degradation mechanisms, though the specific conditions that promote them are not well understood. Dissolved organic carbon promotes denitrification, and many soils are carbon limited or become carbon limited at high nitrate levels (Wenger, 1999).

Both grass and forested riparian buffer zones are effective at reducing nutrients but there is very little agreement among researchers regarding which is more effective. In situations where groundwater flow is relatively deep, trees would appear to be more effective because their roots would be more likely to penetrate into the zone of lateral groundwater flow.

C.1.7.4 Nutrient Supply

Leaf litter is the base food source in most stream ecosystems and streamside trees are critical in establishing this for the aquatic food web. Leaf litter and other organic matter from riparian forests, including terrestrial invertebrates that drop into the water, are an important source of food and energy to stream systems (Wenger, 1999). Small fish, some amphibians, and most aquatic insects rely primarily on leaf detritus (dead leaf material) from trees as food. Studies have shown that when streamside trees are removed, many aquatic insects decline or even disappear, and with them, the native fish, birds, and other species that may depend on them. Some insects are adapted to specific plant species and are unable to reproduce or even survive when fed the leaves from non-native or exotic species (Palone and Todd, 1998).

C.1.7.5 Flood Control

Palone and Todd (1998) provide a good analysis on this topic. Stream corridors and natural forest vegetation help to reduce the downstream effects of floods by dissipating stream energy, temporarily storing flood waters, and helping to remove sediment loads through their incorporation into the flood plain. A vegetated buffer that resists channelization is effective in decreasing the rate of flow, and in turn, increases infiltration. Forests provide as much as 40 times the water storage of a cropped field and 15 times that of grass turf. These increases in storage are largely due to the forest's ability to: capture rainfall on the vast surface area of the leaves, stems, and branches; the porosity and water holding capacity of organic material stored on the forest floor and in the soil; and the greater transpiration rates common to the community of forest vegetation. Increasing width to incorporate the flood plain also increases the potential efficiency of water storage from upstream flow during storm events. Providing flood storage buffers where possible along smaller streams in a watershed may provide a valuable approach to downstream flood reduction. However, once the entire flood plain is included within the buffer area, the effect of buffer width on flood peak reductions is negligible (Palone and Todd, 1998).

C.1.8 Headwater Streams

Headwater streams can vary in appearance, composition, and biota given their geographical location and position on the landscape. In most cases, headwater streams originate at high elevations and usually consist of alternating riffles and runs through small depositional pools. Boulders, cobble, rubble, and bedrock comprise the larger riffle substrates of headwater streams. The substrate of the small pools of headwater streams is usually finer sediment. Large, woody debris commonly contributes to the substrate complexity in headwater streams. The combination of substrate characteristics, varying flow rates, and other flow characteristics, such as hydrologic cycles, flow patterns, load transport and storage, produces the riffles, runs, and pools than can be found in the channels of headwater streams (U.S. EPA et al., 2003).

Headwater streams are generally shaded by riparian vegetation, and in some cases this vegetation may be so thick that the cover prohibits photosynthesis by aquatic primary producers (Molles, 2005). The extent of shading progressively decreases downstream as stream width increases (Molles, 2005). Data from Stout and Wallace (2005) found that biological communities in the study area's streams were present as soon as there was flowing water. Although intermittent headwater streams tend to go dry for a portion of the year, macroinvertebrate life can exist within their channels. In a study of intermittent and perennial streams in Alabama, macroinvertebrate assemblages of normally intermittent streams did not differ greatly from those of nearby permanent or perennial streams (Feminella, 1996).

C.1.8.1 Function of Headwater Streams

Headwater streams serve numerous ecological functions including attenuating floods, maintaining water supplies, and improving water quality (Levick et al., 2008). A primary function of headwater streams is to ensure continuous flow of water to downstream ecosystems. The water level in headwater streams is often higher than the water table which allows water to flow through the channel bed and banks into the soil and groundwater (Levick et al., 2008). During periods of low to no precipitation (e.g., drought), the flows of some downstream reaches of headwater streams are supported by water flowing from the soil and groundwater through the channel banks and bed of the stream (Levick et al., 2008). This exchange of water from the soil and groundwater into the stream maintains stream flow. However, headwater streams are more prone to drying out than downstream segments because they have smaller drainage areas with less recharge potential and occur at higher elevations (McMahon and Finlayson, 2003; Fritz et al., 2008). Headwater streams provide cover, food, and spawning/breeding habitat for various species and provide cover for species that are colonists when downstream ecosystems are experiencing disturbance (Meyer and Wallace, 2001).

The major functions of headwater streams can be summarized into two categories: physical and biological (U.S. EPA et al., 2003). These functions are described below:

Physical

- Headwater streams tend to moderate the hydrograph, or flow rate, downstream.
- They serve as a major area of nutrient transformation and retention.
- They provide a moderate thermal regime compared to downstream waters—cooler in summer and warmer in winter.
- They provide for physical retention of organic material.

Biological

- Biota in headwater streams influence the storage, transportation, and export of organic matter.
- Biota convert organic matter to fine particulate and dissolved organic matter.
- They enhance downstream transport of organic matter.
- They promote less accumulation of large and woody organic matter in headwater streams.
- They enhance sediment transport downstream by breaking down the leaf material.
- They enhance nutrient uptake and transformation.

C.1.8.2 Energy Sources and Primary Production of Headwater Streams

Headwater streams are primary locations of input, storage, transformation, and export of detritus to downstream reaches (Meyer and Wallace, 2001). The interaction between water and sediments in headwater streams supports nutrient and organic matter storage and processing. The bacteria and fungi in headwater streams are the driving force behind leaf decomposition and are sources of food for benthic invertebrates (Meyer, 1994; Meyer and Wallace, 2001). In headwater streams, leaves and other plant materials (i.e., allochthonous inputs) are the primary sources of energy available to the stream ecosystem. Upon entering the stream, the plant material is broken down by microbes and fungi, which are in turn sources of food for shredding and collecting macroinvertebrates (Meyer and Wallace, 2001; Molles, 2005). Although fungi have higher productivity and often contribute more biomass than bacteria in headwater streams, bacteria are also an important source of carbon for aquatic insects (Meyer and Wallace, 2001). Dissolved organic carbon (DOC) from the catchment and channel supports the growth of bacteria in headwater streams (Meyer et al., 1998; Meyer and Wallace, 2001). Fisher and Likens (1973) explain that over 99 percent of the annual energy inputs to a small forested stream can be attributed to leaf detritus and DOC from the terrestrial environment. Given the unidirectional flow of streams, downstream areas are dependent on upstream areas for portions of their energy (per "River Continuum Concept," Vannote et al., 1980). Production of both primary and secondary consumers is connected to the supply of leaf litter from riparian forests and its retention in the channels of headwater streams (Meyer and Wallace, 2001).

Plant communities of higher-gradient streams live in a physically challenging environment. Overall, floras in close proximity to high-gradient streams are subjected to greater current velocities than downstream plant communities, and the surroundings of high-gradient streams are usually densely shaded. Plant communities occurring in high-gradient streams contain species uniquely adapted to survive in this type of environment. The lack of direct anthropogenic (human-induced) disturbance to watersheds of high-gradient streams likely prolonged the persistence of the endemic flora in these areas (Wilcove et al., 1998). Limitations on the availability of water in arid environments results in patchy, sparse vascular plant cover (Levick et al., 2008). As a result, algal and soil microbial activity is important for nutrient cycling in these environments (Belnap et al., 2005).

The ecological functions of plant communities within ephemeral and intermittent streams are poorly understood (Levick et al., 2008). Plant communities along ephemeral and intermittent streams provide structural elements of food, cover, nesting, and breeding habitat, and movement/migration corridors for wildlife that are often not as readily available in the adjacent uplands. Vegetation in ephemeral stream channels plays a key role in resource retention by protecting soils from wind and water erosion, slowing floodwater velocity, and moderating temperatures (Levick et al., 2008). Ephemeral stream vegetation also influences biogeochemical cycles by providing leaf litter, food, and cover for wildlife. In some cases, vegetation can intercept rainfall, preventing it from infiltrating into the soil, thereby influencing the local water balance and ecosystem processes (Owens et al., 2006; Miller, 2005). Vegetation structure and diversity influence wildlife species diversity and abundance; changes in the abundance of plant species or the composition of the plant community may affect an array of ecosystem functions and processes. Functions of these communities include: moderating soil and air temperatures; stabilizing channel banks and interfluves; seed banking and trapping of silt and fine sediment favorable to the establishment of diverse floral and faunal species; and dissipating stream energy which aids in flood control (e.g., Levick et al., 2008).

C.1.9 The River Continuum Concept

U.S. EPA et al. (2003) provided a detailed description of the River Continuum Concept developed by Vannote et al. (1980); that description is included here because it is relevant to the streams and rivers distributed throughout the coal regions of the U.S.

The River Continuum Concept (Vannote et al., 1980) is a theory that details how differing energy sources are processed efficiently, progressing from headwater streams to large rivers. This theory explains that energy sources are dependent upon geomorphological, chemical, and biological factors that have evolved within the surface water ecosystem to create a balanced energy transport. The general metabolism for the river ecosystem uses energy that is transported downstream from upstream reaches within the system. From the headwaters to the mouth of the river, the river ecosystem is comprised of a balanced, efficient, longitudinal gradient of energy sources and processing in which the particle size of organic matter becomes more refined as the river becomes larger.

In each portion of a river ecosystem, some organic matter is processed, some stored, and some released (Vannote et al., 1980). Organic matter is conditioned by microbes (fungi and bacteria), and some is respired (to carbon dioxide) by microbes and animals, some converted to smaller particles and dissolved organic matter which is exported to downstream communities (Vannote et al., 1980). Macroinvertebrate communities at each section of the river ecosystem have become specifically adapted to maximize the processing of energy available in the form of organic matter. Because macroinvertebrate communities serve as a food base for higher trophic organisms (e.g., fish) in the food web, these higher trophic organisms have also evolved to fit available niches in the stream ecosystem.

Headwater streams harbor primarily benthic macroinvertebrate communities who are specialized to feed on the coarse particulate organic matter (CPOM) deposited in the system. Examples of benthic macroinvertebrates include crayfish, worms, snails and flies. The majority of benthic macroinvertebrates in headwater streams are classified as shredders and collectors who feed on the CPOM and fine particulate organic matter (FPOM), and predators who feed on other macroinvertebrates. Typical benthic macroinvertebrates found in headwater streams include insects such as mayflies (Ephemeroptera), stoneflies (Plecoptera), caddisflies (Trichoptera), dragonflies and damselflies (Odonata), beetles (Coleoptera), dobsonflies and alderflies (Megaloptera), true bugs (Hemiptera), springtails (Collembola), and true flies (Diptera). Other macroinvertebrates may include crayfish (Decapoda), isopods (Isopoda), worms (Oligochaeta and Annelida) and snails (Gastropoda).

In the southern Appalachian Mountains, macroinvertebrates of several orders including Ephemeroptera, Plecoptera, and Trichoptera have been found to be rich in species, including many endemic species and species considered to be rare. This diversity and unique assemblage of species has been attributed to the unique geological, climatological, and hydrological features of this region (Morse et al., 1993; Morse et al., 1997). Many biologists agree that the presence of a biotic community with such unique and rare populations should be considered a critical resource. Stream macroinvertebrates are typically classified on the basis of their functional feeding group (Cummins, 1973; Cummins and Klug, 1979; Merritt and Cummins, 1984). Insects within a functional feeding group share similarities in their morphology, feeding behavior, and feeding mechanisms (e.g., scraping, collecting, shredding, filtering). Typical functional feeding groups are described below.

C.1.9.1 Scrapers

Scrapers are adapted to scrape materials, such as algae or periphyton and its associated microflora, from rock or organic substrates, such as leaves (Wallace et al., 1992). Typically scrapers include certain taxa of snails, mayflies, caddisflies, beetles, and fly larvae.

C.1.9.2 Shredders

Shredders chew primarily large pieces of decomposing vascular plants ($\geq$1 mm or 0.039 inch in diameter) along with its associated microflora and fauna. They may also feed directly on living vascular hydrophytes or gouge decomposing wood submerged in streams (Wallace et al., 1992). In addition to aquatic insects, many omnivorous crayfish are facultative shredders. Shredders are important because their mode of feeding causes the generation of large quantities of small organic particles. These particles are more easily transported downstream and may be acted on by microbes more easily due to the increase in the surface area to volume ratio. Common shredders are certain taxa of stoneflies, caddisflies, and fly larvae.

C.1.9.3 Collector-gatherers

Collector-gatherers feed primarily on fine pieces of decomposing particulate organic matter (less than or equal to one millimeter or 0.039 inch diameter) deposited within streams (Wallace et al., 1992). Many Chironomidae larvae are collector-gatherers.

C.1.9.4 Collector-filterers

Collector-filterers have specialized anatomical structures (setae, mouthbrushes, fans, etc.) or silk and silk-like secretions that act as sieves to remove particulate matter from suspension (Jorgensen, 1966; Wallace and Merritt, 1980; Wallace et al., 1992). Some mayflies, caddisflies, and fly larvae are collector-filterers.

C.1.9.5 Predators

Predators feed on animal tissues by either engulfing their prey or by piercing prey and sucking body contents (Wallace et al., 1992). Predators include dragonflies, hellgrammites, crayfish, and some taxa of stoneflies, caddisflies, beetles, and fly larvae.

C.1.10 Primary Production Within Headwater Streams

U.S. EPA et al. (2003) provided the following information about primary production within headwater streams of one coal region; it is included here because of its continued relevance to the coal regions covered in this DEIS.

Primary production is the input of energy into a system by the growth of flora living in the system. Primary production in streams is often measured as mass of carbon or ash free dry mass, which is largely carbon, per unit area, per year. Primary production rates in Appalachian streams have been shown to vary with stream order, season, degree of shading, nutrients, and water hardness (Wallace et al., 1992). Although under some circumstances, gross primary production can be high (Hill and Webster, 1982; Wallace et al., 1992), typical primary production inputs appear to range from approximately nine to 446 pounds of carbon per acre of stream per year (Keithan and Lowe, 1985; Rodgers et al., 1983; Wallace et al., 1992).

Levick et al. (2008) noted that plant productivity in arid and semi-arid regions, which include multiple coal regions, is often low most of the year and punctuated by bursts of activity following rain and runoff events. Variations of the patterns of primary productivity and evapotranspiration by plant communities are dependent on their main sources of water: direct precipitation, channel flow, or stored water (de Soyza et al., 2004; Leenhouts et al., 2006; Levick et al., 2008). When stored water is accessible, productivity and evapotranspiration of plant species can be high for much of the growing season (Atchley et al., 1999). De Soyza et al. (2004) found that plants along an ephemeral stream channel responded more to channel flow than direct precipitation, indicating the importance of maintaining intact channel networks throughout a watershed.

C.1.11 Vascular Plants and Bryophytes

Vascular plants (ferns and higher plants) and bryophytes (mosses and liverworts) are common in areas surrounding headwater streams, but the structure and composition is dependent on the relief of the landscape, climate, size of stream, soil chemistry, substrate, and flow patterns (U.S. EPA et al., 2003). In ephemeral and intermittent streams, the structure and composition of the vegetation is related to the size of the stream and patterns of flow, although most of the diversity is comprised of herbaceous species (Bagstad et al., 2005; Levick et al., 2008). Vascular plants found in or near high-gradient streams typically have adventitious roots, rhizomes, flexible stems, and streamlined narrow leaves (Westlake, 1975; U.S. EPA et al., 2003). In contrast, bryophytes contribute the majority of the biomass of primary producers in small streams, and they attach to rocks and boulders and are smaller in size, lack flowering parts, and reproduce by releasing spores. Given their dominance within these areas, bryophytes also provide habitat that supports many aquatic invertebrate species (Meyer et al., 2007). Mosses are most diverse and abundant in headwater streams and seeps, and they can exclusively use carbon dioxide in photosynthesis (Meyer et al., 2007). Heino et al. (2005) noted that bryophyte species richness ranged from 0 to 14 species in small boreal streams. Glime (1968) found that four species dominate the bryophyte flora of small, high-gradient Appalachian streams and that *Fontinalis dalecarlica* and *Hygroamblystegietum fluviatile* are most abundant in first through third-order streams.

In regions subjected to seasonal precipitation, depth to groundwater is particularly important because groundwater is closely coupled with stream flow that maintains a water supply to riparian vegetation (Groeneveld and Griepentrog, 1985; Levick et al., 2008). The species composition of ephemeral and intermittent streams within the arid and semi-arid southwestern U.S. is dependent on species composition of the watershed and floristic province, as well as with drainage size, climatic regime, latitude, longitude, elevation, aspect, and soil characteristics (Levick et al., 2003). As the hydrologic regime shifts from perennial to ephemeral, vegetation composition shifts towards more drought-tolerant species, vegetation cover declines, riparian woodlands give way to riparian shrublands, and canopy height and upper canopy vegetation volume decline (Leenhouts et al., 2006; Stromberg et al., 2007; Levick et al., 2008).

C.1.12 Algae

Algae are prevalent in headwater streams, and multiple species are endemic to specific streams in the U.S. (U.S. EPA et al., 2003; Meyer et al., 2007). As summarized in Wallace et al. (1992), the algae of high-gradient streams are limited to species capable of anchoring to stable substrates, preferably large stationary objects (U.S. EPA et al., 2003). In systems where the headwaters are shaded and low in nutrients, 30 to 60 algal species are commonly encountered (Meyer et al., 2007). During periods of low flow, algae may temporarily colonize smaller objects (U.S. EPA et al., 2003).

C.1.13 Woody Material

Woody material is not just an energy source but also provides other important stream functions involving hydrology and habitat structure. Such functions of woody debris in streams include: contributing to stair-step stream bed profiles that result in rapid dispersion of the stream's energy; forming micro-pools or sieve-like structures that retain other particulate organic material which may influence trophic and nutrient dynamics; providing habitat for aquatic organisms; and functioning as a food source for xylophagous organisms (Wallace et al., 2001; U.S. EPA et al., 2003).

C.1.14 Organic Matter Processing and Nutrient Cycling

The headwater stream (first- through third-order) is the origin for energy processing within the river ecosystem. Headwater streams located in forested areas are characterized by a dense canopy and low photosynthetic production. Allochthonous (coming from outside the system) materials derived from the terrestrial environment are the primary sources of energy for headwater streams. As summarized in U.S.

EPA et al. (2003), most allochthonous material arrives in the form of CPOM (greater than one millimeter or 0.039 inch in size). Smaller amounts of other allochthonous materials that are transported to the stream include FPOM (50 µm to one µm in size or 0.0019 to 0.000039 inches in size) and Dissolved Organic Matter (DOM) traveling in surface-water and groundwater flows. Microbes and specialized macroinvertebrates living in headwater streams, called shredders, feed on CPOM, converting it into FPOM and DOM. The FPOM and DOM are carried downstream to mid-sized streams (U.S. EPA et al., 2003).

Because mid-sized streams (fourth- through sixth-order) are wider than headwater streams, the canopy is usually more open and more light is able to penetrate to the stream bottom. As a result, a greater abundance of algae and aquatic plants are able to grow here. In general, the proportion of allochthonous material derived from terrestrial vegetation in mid-sized streams is less than in the headwater streams. Autochthonous material (material that is derived from within the stream) becomes an important component of the energy budget in mid-sized streams. Consequently, mid-sized streams may exhibit a shift from a heterotrophic to an autotrophic system, or one that generates its own energy through photosynthesis. The biological community of mid-sized streams differs somewhat from that in headwater streams in part because of the more diverse types of energy sources that are available. Specialized macroinvertebrates called collectors-filterers and collector-gatherers break down the FPOM carried from upstream reaches into Ultra-fine Particulate Organic Matter (UPOM) (0.5 to 50 nm in size or 0.019 to 1.97×10^{-6} inches in size). These macroinvertebrates, as well as microbes, also consume living plant matter (algae and aquatic plants) converting it into additional forms of energy. The UPOM derived from these energy sources is then carried downstream to larger rivers. Interestingly, collectors can also increase particle sizes in some cases by feeding on material in the several micron range and defecating compacted feces of a much larger particle size. These larger particles then become available to larger particle feeding detritivores (Wallace et al., 1992).

As summarized in U.S. EPA et al. (2003), larger rivers (seventh- through twelfth-order) have different biological communities from lower order streams. The increased width, depth, and suspended mineral and organic matter prohibit much light penetration and consequent growth of algae and plants within the main channel. Collectors again become the primary macroinvertebrate community to process the particulate organic material. Larger rivers tend to be heterotrophic systems. Several models have been developed to describe the movement of energy and nutrients in rivers. These theories include the River Continuum Concept (Vannote et al., 1980) and the concept of nutrient spiraling (e.g., Webster, 1975). The development of the River Continuum Concept greatly improved the scientific communities' understanding of the ecosystem-level functions of rivers and provided direction for lotic ecosystem research over the last 30 years.

C.1.15 Invertebrates

Invertebrates form a major portion of Earth's animal diversity, and the emergence of aquatic invertebrates from streams is a significant part of the food chain (Levick et al., 2008). Invertebrate inhabitants of headwater streams are sources of food to fish, mammals, and amphibians within the headwater reach (Meyer et al., 2007). Emerging and flying adults of aquatic insects are often sources of food for terrestrial animals (e.g., spiders, birds, and bats), and they represent an important reciprocal link between streams and terrestrial biota (Baxter et al., 2005; Meyer et al., 2007).

The communities found within streams are dependent upon the stream type and order. Headwater streams harbor primarily benthic macroinvertebrate communities (e.g., crayfish, worms, snails, and insects), which are specialized to feed on CPOM (U.S. EPA et al., 2003). Ephemeral and intermittent streams also harbor diverse invertebrate communities because of their array of microhabitats (Levick et al., 2008). Disturbances caused by intermittent flows may facilitate high food quality and consequently high levels of insect production in warm-temperate desert streams (Fisher and Gray, 1983; Jackson and Fisher, 1986; Grimm and Fisher, 1989; Huryn and Wallace, 2000). Most benthic macroinvertebrates in headwater streams are classified as shredders and collectors that feed on the CPOM and FPOM, and predators that feed on the other macroinvertebrates (U.S. EPA et al., 2003). For example, common benthic macroinvertebrates found in headwater streams of Appalachia include insects such as mayflies (Ephemeroptera), stoneflies (Plecoptera), caddisflies (Trichoptera), dragonflies and damselflies (Odonata), beetles (Coleoptera), dobsonflies and alderflies (Megaloptera), true bugs (Hemiptera), springtails (Collembola), and true flies (Diptera) (U.S. EPA et al., 2003). Other macroinvertebrates may include crayfish (Decapoda), isopods (Isopoda), worms (Oligochaeta and Annelida) and snails (Gastropoda).

Mollusks have been receiving more research attention, and their importance as a part of stream communities is receiving greater recognition. Mollusks tend to be more diverse in larger, perennial streams but can persist and be present and abundant in headwaters (Meyer et al., 2007). Mollusks such as bivalves and gastropods are common in lotic systems. Mussels are among one of the most diverse groups in North America, especially in the southeast U.S.; however, they are among the most threatened as a result of habitat loss, degradation, and invasive species. Crustaceans, such as amphipods, isopods and crayfish, are prevalent in headwaters. The southeast U.S. also has the greatest crayfish diversity in the world, but many of these species are facing similar dangers to that of freshwater mussels. Microcrustaceans, such as cladocerans, ostracods, and copepods, also live in headwaters, where their populations can attain high densities (>10,000 m^2) (Galassi et al., 2002; Meyer et al., 2007). Small streams support many invertebrate taxa other than insects, mollusks and crustaceans, but these groups have not received much study. A typical headwater stream might contain 30 to 300 species and 20,000 to 2,000,000 / m^2 of these other taxa, such as turbellarians, gastrotrichs, and nematodes (Meyer et al., 2007). Species richness in these groups may be as high in headwaters as in larger streams and many can be found in intermittent streams (Meyer et al., 2007).

C.1.16 Vertebrates

Fish and amphibians are the major groups of vertebrates that inhabit streams, and multiple headwater streams serve as habitat to species that are endemic to specific areas. Fish species present in headwater streams tend to be representative of cold water species (e.g., darters, sculpins, salmonids, cyprinids) and are primarily sustained by a diet of invertebrates (Vannote et al., 1980). Fish populations can be abundant in headwater streams, but their diversity generally increases with increasing stream size, habitat heterogeneity, pool development, and habitat volume. Although fish tend to occupy larger streams, multiple species can use ephemeral and intermittent streams as habitat. Many fishes found in headwaters are unique and likely contribute to network-wide diversity and play a critical role in the genetics of fish populations (Meyer et al., 2007; Palmer, 2009). In mid-sized streams, a shift in the fish community from cold-water to more warm-water fish species usually occurs. Furthermore, the fish community becomes more diverse and more piscivorous species are present (Vannote et al., 1980).

Amphibians, in regions where present, play a critical role in the biodiversity of stream communities. In streams where fish are absent, amphibians tend to be the most common vertebrate and dominant aquatic predators (Bernhardt and Palmer, 2011). Salamanders are the most common amphibians in headwaters (Davic and Welsh Jr., 2004), but frogs, toads, and reptiles (e.g., snakes and lizards) can also be abundant (Meyer et al., 2007). Predation by fish is believed to restrict amphibians to the smaller streams or the banks of large streams (Wallace et al., 1992; Bernhardt and Palmer, 2011). Ephemeral and intermittent streams serve as crucial habitat for amphibians, perhaps because they offer freedom from predators; some of these species are state and/or federally threatened or endangered (Davic and Welsh Jr., 2004; Bernhardt and Palmer, 2011). Amphibian production in first and second order streams is often greater than production within higher-order streams (Wallace et al., 1992). Multiple specialized stream salamanders require headwater seeps and small streams in forested habitats to maintain viable populations (Petranka, 1998). Plethodontids, or lungless salamanders, use small headwater streams as their principal larval habitat, where they spend from a few months to five years (Beachy and Bruce, 1992). Salamander populations from headwater streams influence insect population dynamics by predation, regulate detritus food webs, and link stream and terrestrial food webs (Davic and Welsh Jr., 2004). Reptiles also contribute to the biodiversity of streams. Multiple species of turtles, lizards, and snakes use streams to obtain food. In headwaters, snakes and turtles primarily comprise the reptilian communities (Meyer et al., 2007). Although reptiles are not usually restricted to or most abundant in these habitats (Buhlmann and Gibbons, 1997), species in several genera (e.g., *Nerodia*, *Farancia*, and *Regina*) specialize on aquatic prey items (Meyer et al., 2007).

C.2 LENTIC (Non-Flowing) Aquatic Systems

Lentic aquatic systems are defined as non-flowing water bodies such as natural lakes and ponds or artificial impoundments such as a reservoir. Lentic systems are also referred to as lacustrine habitats, which may include palustrine habitats as described below. Lentic water bodies can be permanently flooded, intermittent (e.g., playa lakes), or have a tidal influence where ocean-derived salinities are below 0.5 percent (Cowardin et al., 1979). Some lentic systems may be fresh water bodies, while others have varying levels of salinity (e.g., Great Salt Lake).

Lakes are generally differentiated from ponds based on their size, with lakes being larger; however, the usage of terminology can differ. Another distinction that can be made between lakes and ponds would be the type of mixing that occurs. Water bodies may be considered lakes when the wind plays the dominant role in mixing (Menzel and Cooper, 1992). Cowardin et al. (1979) indicates that lakes typically have extensive areas of deep water and considerable wave action. In ponds, gentler convective mixing predominates. Ponds can include pools of water such as ephemeral or vernal pools which are formed by winter and spring rains and/or snow melt, and that typically dry up by summer months.

Lacustrine water bodies differ from palustrine (inland wetlands and marshes) in that they are larger (generally greater than 20 acres), deeper (generally deeper than 6.6 feet at low water), and vegetation does not exceed 30 percent aerial coverage. Palustrine systems consist of non-tidal wetlands dominated by trees, shrubs, and other vegetation, and where ocean-derived salinities are below 0.5 percent (Cowardin et al., 1979). Many wetland types are generally grouped within lentic systems where wetlands have constant soil saturation or inundation with distinct flora and faunal communities. Cowardin et al. (1979) distinguishes deepwater habitats from wetlands; however, shallow and permanent or intermittent ponds/pools can be considered to be a type of palustrine wetland.

C.2.1 Physical Characteristics

Natural lakes are formed by many different processes to include catastrophic phenomena (glacial, volcanic, and tectonic forces), rivers, waves, and rock solution. Human constructed lakes are created by dams or excavation of basins. Lake classifications are determined by the method in which they formed and include glacial lakes, tectonic basins, volcanic lakes, landslide solution lakes, plunge pools, oxbow lakes, and beaver-made or human-made lakes (U.S. EPA, 2008). In geological terms, most natural lentic systems are young, dating from the last glacial period (Thorp and Covich, 2001). The source of water for many lentic systems is dependent on surface runoff and by groundwater input; groundwater may provide the majority of the water to some ponds (Menzel and Cooper, 1992). Most natural and man-made lentic systems have average depths of less than 20 meters (Wetzel, 2001).

The structure of a lake or pond is defined by physical, chemical, and biological characteristics. In some instances, landscape position of the watershed basin, characteristics of the watershed, and morphometry of the basin are a more important than basin formation for describing the biological features of a lake (U.S. EPA, 2008). Watershed conditions can greatly affect lakes, ponds, and impoundments to include allochthonous (organic material produced outside the stream such as leaves, wood) and autochthonous (primary production by plants and algae present within the system) material depending on the type of setting. Further, any changes to energy sources (i.e., terrestrial detritus versus algae in more open water bodies) can influence the food base and community structure (Menzel and Cooper, 1992).

Environmental conditions of lentic systems differ greatly with that of lotic systems. Unidirectional water flow is minimal, and lentic waters tend to be warmer than streams and rivers. Oxygen levels in lentic systems are generally lower than lotic systems, but some standing waters may contain enough dissolved oxygen to support the growth of some lotic adapted organisms (Mayer and Laudenslayer, 1988).

The limnology of lakes is dominated by vertical gradients. The vertical distribution of lake organisms is influenced by gradations of oxygen, light, and temperature in addition to currents and seiches (oscillating waves). Light penetration of lentic systems is dependent on turbidity. Temperatures will vary seasonally and with depth. Oxygen content of lakes and ponds is low compared to systems with flowing water as a smaller proportion of surface water is in direct contact with the atmosphere and because decomposition is taking place and using significant portions of the oxygen supply within the system (Mayer and Laudenslayer, 1988). However, lakes and reservoirs may retain some river-like qualities such as longitudinal gradients in channel morphology, flow velocity, water temperatures, bottom substrate type, and biotic community composition. Many biological, chemical, and physical processes in lakes and reservoirs are similar to rivers (Menzel and Cooper, 1992).

C.2.2 Ecological and Biological Functions

Lentic systems provide many functions: providing habitat for organisms, providing drinking water, waste removal, agricultural irrigation, industrial activity, and recreation (Hairston and Fussmann, 2002). Ecological functions of larger lakes and ponds may include flood control and improved water quality of riparian systems downstream through the temporary removal of nutrients and toxic materials by allowing these compounds to settle out of the water column. Ecosystem-level functions occurring within lentic systems include energy flow relationships. Small lentic systems, such as ponds, have a limited ability to cycle nutrients on a watershed scale (Menzel and Cooper, 1992). Due to the high ratio of drainage area to surface area, reservoirs have high annual nutrient loads compared to natural lakes. The movement of nutrients and energy in reservoirs is a major function of these systems and is closely tied to the physical environment (Soballe et al., 1992).

Organic matter inputs enter the reservoir system, which support the growth of bacteria, fungi, and detritivores. Phytoplankton production dominates most impoundments as changing water levels inhibit development of littoral macrophyte and periphyton communities. Sedimentation of detrital aggregates and zooplankton fecal pellets provide an energy source to benthic decomposers which in turn are used by higher level consumers. Nutrient regeneration occurs at most levels of this food web (Soballe et al., 1992).

Lake ecosystems are influenced by their watersheds including the geological, chemical, and biological processes that occur on the surrounding land and within its associated waterways. The open water system, shoreline systems, and upper watershed systems are interrelated and interdependent (Campbell et al., 2006). Lakes are connected to the watershed by the movement of surface water, groundwater, and living organisms. Rivers and streams supply lakes with water and nutrients, and provide spawning and nursery areas for anadromous fish. The health and biodiversity of a lentic system is directly related to the health of each component of the ecosystem. For example, a lentic system can be adversely affected by riparian vegetation removal in the upper watershed, resulting in increased sediment loads and degradation or destruction of anadromous fish spawning habitats (Campbell et al., 2006).

Lentic systems can be divided into several abiotic zones based on distance from shore, light penetration, and temperature change; these zones include photic, aphotic or profundal, and littoral. The photic zone extends to a depth where light penetration is at or above one percent (i.e., the zone where photosynthesis can occur) and where primary producers and most animals live (Thorp and Covich, 2001). The near-shore and shallow area of the photic zone where rooted macrophytes establish is termed the littoral zone. The littoral zone is where the light reaches all the way to the bottom of the lake. Cowardin et al. (1979) defined the littoral zone as the zone that extends from the shoreward boundary to a depth of two meters (6.6 feet) below low water or to the maximum extent of non-persistent emergent vegetation if growing at depths greater than two meters. The littoral zone typically occurs at the edges of lakes and is found throughout most ponds. The photic zone also contains the limnetic zone or open water zone. All water located away from the shore and littoral zone is termed the limnetic or pelagic zone. The limnetic zone is shallower in turbid water than in clear and is a more prominent feature of lakes than of ponds. Below the limnetic zone is the aphotic or profundal zone. The profundal zone has depths beyond which primary producers can live.

Because there is no single, directional flow in a lentic system, stratification may occur. The limnetic zone of a lentic system is classified into thermal layers, depending on the degree of mixing that occurs. The density of water changes with temperature causing lakes to become layered, or stratified, into temperature zones (Dodson, 2005). The temperature of the upper layers will drop as air temperatures drop. As these upper water layers cool they become denser, eventually they becoming dense enough to sink. As the dense layer sinks, it displaces the water at the bottom of the water body, which forces the lower water layers to the surface.

Most lentic systems in North America become stratified during warmer seasons with a layer of lighter water called the epilimnion, which floats over a denser layer (the hypolimnion). During the warmer months the epilimnion is warmer. The two zones are separated by another layer (the metalimnion) where rapid temperature changes occur. Where the shift in temperature changes most rapidly, this layer is called the thermocline (Dodson, 2005).

Oxygen concentrations and stratification depend on the thermal stratification and biological activity within a lentic system and results in three major patterns variation associated with depth: orthograde, clinograde, and heterograde. Oxygen saturation throughout a lake results in an orthograde pattern. Less oxygen is present where water is warmer; oxygen content will be higher in the hypolimnion when the epilimnion is warmer. Bacterial decomposition of organic material in the hypolimnion results in a clinograde pattern where oxygen has been depleted from the hypolimnion layer and respiration and decomposition have increased as lake productivity increases. This is due to the contribution of oxygen to the epilimnion layer from phytoplankton and the removal of oxygen from the hypolimnion layer from decomposition. Algal growth during the summer months will increase productivity which results in turbid conditions, less light penetration, and additional organic material in the hypolimnion layer. The bacterial metabolism of this organic material can reduce oxygen levels in the hypolimnion. The heterograde patterns result from maximum oxygen concentrations at an intermediate depth. This anomaly is found in lakes with low productivity, in which light penetrates into the hypolimnion and algae flourish (Dodson, 2005). Seasonal mixing, as described above, can redistribute these patterns of oxygen concentrations.

Water chemistry plays an important role in lake dynamics, as nutrients influence algal productivity and higher trophic levels (Thorp and Covich, 2001). In deep lakes, the bottom layer has little oxygen when it is not mixing, and few organisms survive there. Similarly, very salty lakes contain only a few highly specialized zooplankton. The hypolimnion is lower in oxygen, higher in nutrients, and has different chemical concentrations due to the minimal exchange of water during stratification. Lake turnover occurs when this stratification breaks down and much or all of the water mass re-circulates (Thorp and Covich, 2001). Some lakes never mix completely, resulting in a circulation only in the upper zones, leaving the lower zones devoid of oxygen where nutrients accumulate over time. Wind easily mixes shallow lakes, so these layers either do not persist or do not develop.

C.2.2.1 Plant Communities, Energy Sources, and Primary Production

Plant communities in ponds and lakes consist of submerged, floating and emergent vascular plants, phytoplankton, and periphyton. Autotrophic bacteria may also occur in lentic systems and contribute to the primary production of these systems. Bacteria and fungi are the major decomposers in smaller lentic systems such as ponds, and, although these organisms may occur as part of the planktonic community, the vast majority of bacteria and fungi are found in or on the sediment layer (Menzel and Cooper, 1992). Phytoplanktons (predominantly filamentous algae) carry on photosynthesis in open water and form the base of a lake’s food chain (Mayer and Laudenslayer, 1988). These primary producers fall into five major categories: diatoms (Bacillariophyta); green algae (Chlorophyta); golden algae (Chrysophyta); blue-green algae (Cyanobacteria); and dinoflagellates (Dinophyta). Very productive lakes are much less clear due to abundant algal blooms (Menzel and Cooper, 1992).

Species distribution of small ponds generally differs from that of large impoundments and lakes. Blue-green algae are often dominant in small lentic systems where nutrient levels are high. In small ponds, benthic algae and periphyton may detach and become part of the planktonic community, and phytoplankton can be reduced greatly depending on surface area coverage by floating macrophytes. This shading effect can also suppress periphyton growth attached to macrophytes or bottom surfaces (Menzel and Cooper, 1992).

Vascular plants in small lentic systems include species with submergent, floating-leaved, or emergent growth forms. Submergent macrophytes are found rooted in benthic sediments at depths from three to 12.5 feet depending on light penetration and may occur in patches or may cover the entire bottom of ponds. Floating or floating-leaved vascular plants may be very abundant in small ponds/impoundments if nutrients are present. Where these plants are found in abundance, they may reduce the photosynthesis in the hypolimnion resulting in an increase in water column respiration. This may result in anoxic conditions (low amounts of oxygen) in the water column, leading to the elimination of fish in the pond (Menzel and Cooper, 1992).

Emergent aquatic and semi-aquatic plants are common along the shoreline of many smaller lentic systems where water depths are shallow (less than one meter) and where sediments have accumulated over time. Common emergent species include cattails (*Typha* spp.), willows (*Salix* spp.), rushes (*Juncus* spp.), and sedges (*Carex* spp.). Emergent plants provide food and habitat for numerous vertebrate wildlife species and are an important energy source for small impoundments (Menzel and Cooper, 1992).

C.2.2.2 Animal Communities

Animal communities in lentic systems live in either the benthos or water column zone and may transition between these two zones during their lifecycle. Groupings of animal communities include invertebrates (e.g., zooplankton, worms, mussels, crustaceans, and insects) and vertebrates (e.g., fish, reptiles, and birds). These groups may heavily use vegetated portions of the benthos for feeding and breeding. Many aquatic animals exhibit complex life cycles and use separate habitats at different stages of their life history (Wilbur, 1980). For example, stream-dwelling fishes may migrate between lotic and lentic habitats to enhance growth or reduce mortality (Dempson et al., 1996; Erkinaro et al., 1998). Movements of stream-dwelling fishes and crayfish between habitats can be affected by various environmental factors such as water levels and temperatures. Movement between habitats can strongly modify population structure, overall density, and the probability of local extinction in both lotic and lentic habitats (Schlosser, 1995).

Major zooplankton assemblages in freshwater systems include rotifers, cladocerans, and copepods (Thorp and Covich, 2001). Rotifers and protozoans comprise a small fraction of total biomass but are numerically abundant and can contribute substantially to energy flow in smaller lentic ecosystems. Zooplankton occupy the regions of high light intensities (i.e., on the surfaces of the pelagic and the littoral zones), feeding on single-celled or small colonial algae. In clear, relatively unproductive lakes, zooplankton consume much of the algae. Some of the zooplankton members also inhabit the benthic zone feeding on detritus and sinking phytoplankton. Zoobenthos greatly increase the secondary productivity in ponds through high growth rates (Menzel and Cooper, 1992).

There are a number of benthic macroinvertebrates found in lentic systems including oligochaetes, crustaceans, and a variety of insects. Macroinvertebrates can be abundant in littoral zones. Those found in the pelagic zone are typically confined to the benthic zone, but some may feed in the water column (Menzel and Cooper, 1992). Small crustaceans, hydras, and snails live in or on surface sediments (Mayer and Laudenslayer, 1988). Macroinvertebrates can greatly increase secondary production in smaller lentic systems (Menzel and Cooper, 1992).

Fishes occupy the littoral, pelagic, and occasionally profundal zones when the dissolved oxygen content is sufficient. Vertebrates in lentic systems may also include various species of frogs, turtles, and water snakes. Survival of many anuran populations depends upon the temporary nature of smaller breeding pools and ponds. Some species do well in relatively deep, permanent ponds (e.g., *Rana catesbeiana*, *Rana palustris*), whereas others require relatively shallow, temporary ponds (e.g., *Bufo* spp., *Hyla chrysoscelis*) (Jansen et al., 2003).

Appendix D. Migratory Birds[4]

D.1 Introduction

It is estimated that 500 species of birds annually migrate from North American breeding grounds for warmer climes and favorable food conditions farther south. Some species travel only as far as the southern U.S., while others continue to Central or South America. The U.S. Fish and Wildlife Service (FWS) administers a variety of laws protecting wildlife and plant species, including the Migratory Bird Treaty Act, 16 U.S.C. §§ 703-712. Because all coal regions lie within migratory bird pathways, the Office of Surface Mining Reclamation and Enforcement (OSMRE) is entering into a Memorandum of Understanding (MOU) with FWS to strengthen migratory bird conservation through enhanced collaboration. This MOU, in support of Executive Order 13186, focuses on avoiding or minimizing avian stressors on migratory birds with an emphasis on species of concern and their habitats, and by identifying areas of cooperation. The goal of this MOU is to promote migratory bird conservation by incorporating conservation measures into agency actions and planning processes whenever possible.

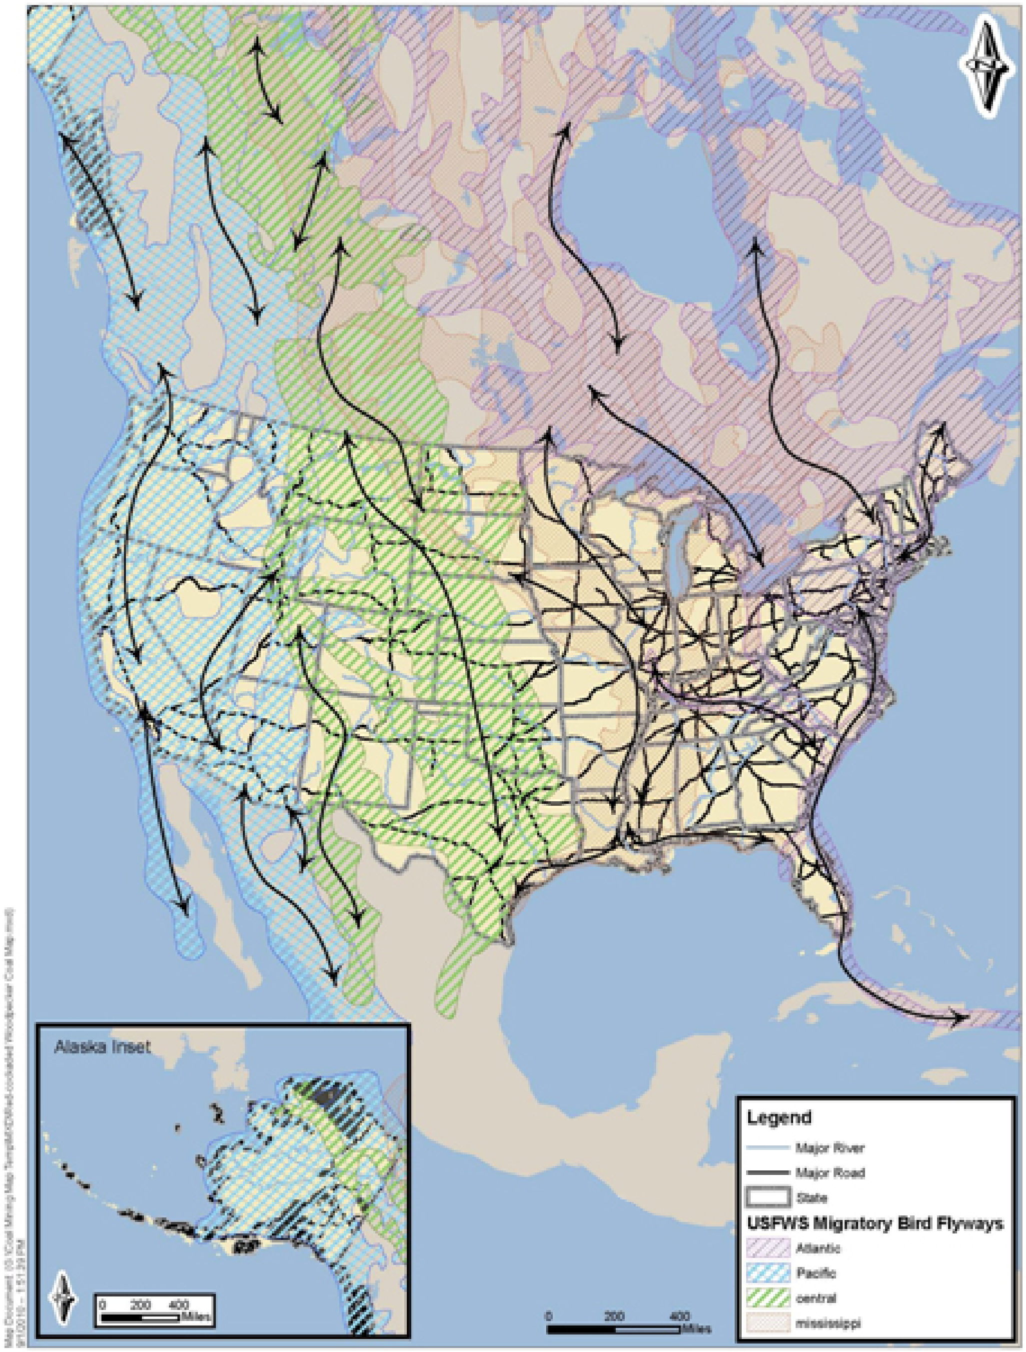
D.2 Migratory Flyways

As depicted in Figure D-1,there are four major North American flyways (Lincoln, 1935):

- Atlantic;
- Mississippi;
- Central; and
- Pacific.

[4] This information is provided as background information in support of the discussions contained within the FEIS. Corrections have been made where necessary in response to comments on the DEIS, however OSMRE has not updated this information since publication of the DEIS.

Figure D-1. North American Flyways



Some of the coal regions are located within more than one flyway. The flyways often overlap in the northern breeding and the southern wintering grounds. Table D-1 reflects the U.S. coal regions and the flyways that occur in each region.

Table D-1. Occurrence of U.S. Coal Regions in Migratory Bird Flyways

COAL REGIONS	Atlantic Flyway	Mississippi Flyway	Central Flyway	Pacific Flyway
Appalachian Basin	X	X		
Colorado Plateau			X	X
Gulf Region	X	X	X	
Illinois Basin		X		
Northern Rocky Mountains and Great Plains			X	X
Northwest				X
Western Interior		X	X	

The four major North American flyways are discussed in greater detail in the following paragraphs.

D.2.1 Atlantic Flyway

Two coal regions are located within the Atlantic Flyway: the Appalachian Basin and the Gulf Region. The Atlantic Flyway can be described as extending from the offshore waters of the Atlantic Coast west to the Allegheny Mountains, then curving northwestward across northern West Virginia and northeastern Ohio, continuing to Canada (the Northwest Territories) and to the Arctic Coast of Alaska. The flyway contains several primary migration routes. The coastal route of the Atlantic Flyway follows the Atlantic shoreline, originating from the north in the eastern Arctic islands and the coast of Greenland. This route from the northwest is important to migratory waterfowl and other birds, including ring-necked ducks (*Aythya collaris*), canvasbacks (*Aythya valisineria*), redheads (*Aythya americana*), and lesser scaups (*Aythya affinis*) (Montalbano et al., 1985). During migration, studies have found that the coastal migration route is predominantly used by many species of songbirds as well as 80% of juvenile raptors and the Appalachian mountains route is used by predominately adult birds although not inclusively, but both routes are of great importance as migration pathways.

D.2.2 Mississippi Flyway

Four coal regions are located within the Mississippi Flyway: the Appalachian Basin, the Gulf Region, the Illinois Basin, and the Western Interior.

The Mississippi Flyway is an important route used by large numbers of ducks, geese, shorebirds, blackbirds, sparrows, warblers, and thrushes. The eastern boundary of the Mississippi Flyway runs through the peninsula of southern Ontario to western Lake Erie, then southwest across Ohio and Indiana and south to the mouth of the Mississippi (U.S. FWS, 2012b). The western boundary is less precise than the eastern boundary of the Flyway and merges into the Central Flyway. The longest migration route of any in the Western Hemisphere is found within the Mississippi Flyway; the northern terminus is on the Arctic coast of Alaska and its southern end is located in Patagonia, Argentina. For more than 3,000 miles, from the mouth of the Mackenzie River in northern Canada to the delta of the Mississippi, this route is uninterrupted by mountains; the greatest elevation above sea level is less than 2,000 feet. The presence of the two rivers (oriented north-south) and the well-timbered land provide ideal conditions to support migrating birds (Weitzell et al., 2003). The Mississippi Flyway is important to the declining American black duck (*Anas rubripes*) population (Brook et al., 2009), the recovering wood duck (*Aix sponsa*) population (Bellrose, 1976), mallards (*Anas platyrhynchos)* (Green and Krementz, 2008), and many other waterfowl and bird species.

D.2.3 Central Flyway

Four coal regions are located in the Central Flyway: the Northern Rocky Mountains and Great Plains, the Colorado Plateau, the Western Interior, and the Gulf Region.

It may be called "the flyway of the Great Plains" as the Central Flyway encompasses the vast central region of the U.S. lying between the valley of the Mississippi River and the Rocky Mountains (U.S. FWS, 2012b). The Central Flyway is relatively simple, as the majority of the birds that use it make direct north and south journeys from breeding grounds in the north to winter quarters in the south. The Central Flyway enters the northern U.S. in Montana and birds travel in the central part of the U.S. (Montana, Wyoming, South Dakota, Nebraska, Kansas, Oklahoma, Colorado, New Mexico and Texas). The Central Flyway then follows the coast of the Gulf of Mexico southward. The western boundary closely follows the eastern side of the Rocky Mountains. However, in western Montana, the continental divide is crossed and the line passes through the Great Salt Lake Valley. The northern end of the Great Salt Lake is also an important breeding area for waterfowl. Waterfowl breeding in Canada and in much of the north central U.S. use the Central Flyway for migratory stopover sites and wintering habitat.

D.2.4 Pacific Flyway

Three coal regions are located within the Pacific Flyway: the Northern Rocky Mountains and Great Plains, the Colorado Plateau, and the Northwest.

The Pacific Flyway enters the U.S. from Alaska through Canada via Washington, Idaho, and Montana, and migratory birds travel through Washington, Idaho, Montana, California, Nevada, Utah, and Arizona (U.S. FWS, 2012b). At the U.S. / Canada border, the flyway routes branch: large flights continue southeastward along the foothills of the Rocky Mountains and into the Central and Mississippi flyways, while other migratory birds turn southwestward across northwestern Montana and the panhandle of Idaho, following the Snake and Columbia River valleys to the interior valleys of California. Suitable winter quarters for birds are found in California from the Sacramento Valley south to Salton Sea and in the tidal marshes near San Francisco Bay. The Central Valley is an important stopover site for migrating shorebirds and waterfowl in the Pacific Flyway (Shuford et al., 1998). The Central Valley supports 20 percent of waterfowl wintering in the U. S. and 60 percent wintering in the Pacific Flyway (Shuford et al., 1998).

D.3 Discussion

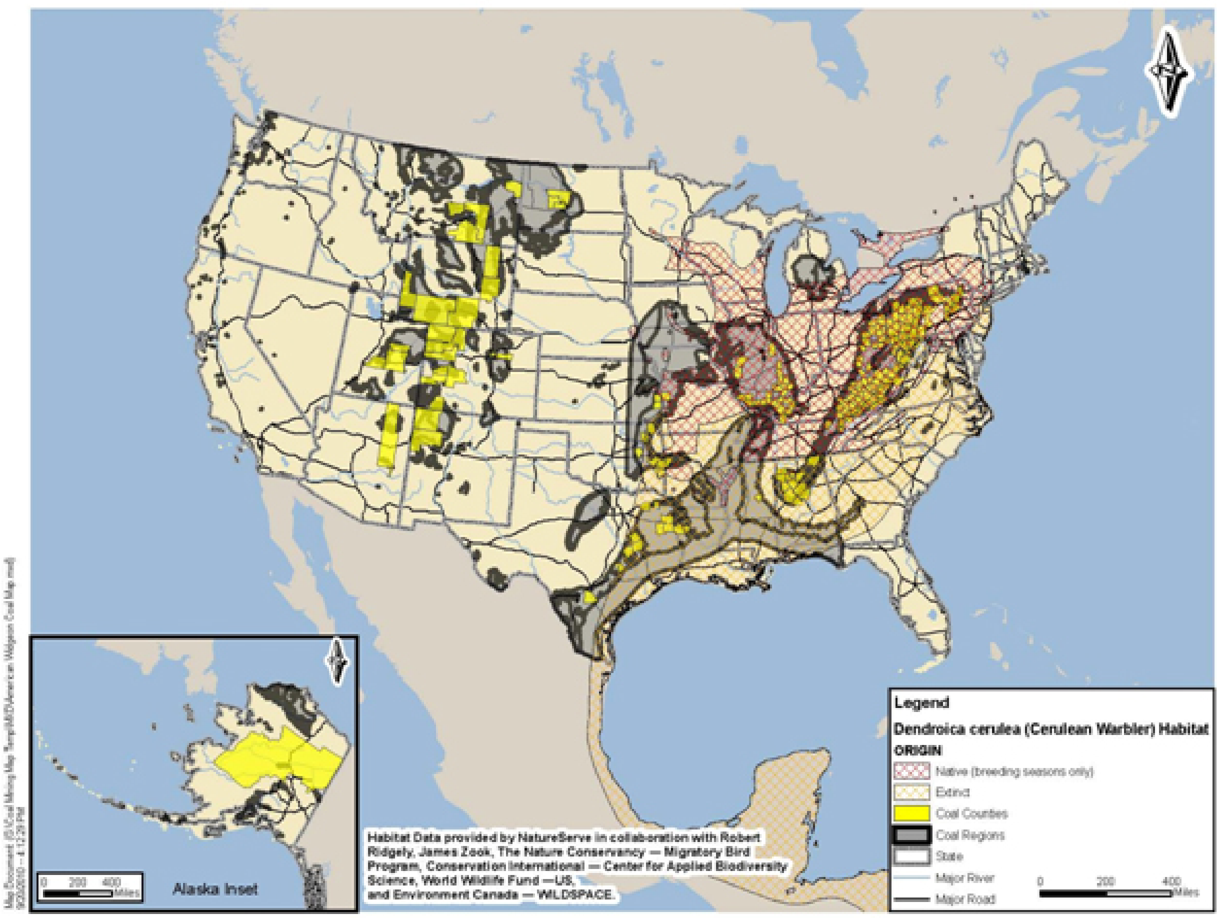
Migrating birds require places along the way that provide an adequate food supply for the quick replenishment of fat reserves, rest and shelter from predators, and water for rehydration. These places are often referred to as stopover sites. A few important general land types that are important are: riparian woodlands and corridors; shelter belts and hedgerows in agricultural areas; desert oases; and mountain meadows. A primary characteristic of these stopover sites is the presence of a water body, which are sometimes on Surface Mining Control and Reclamation Act of 1977 (SMCRA) permitted land. This Draft Environmental Impact Statement (DEIS) covers a broad area which includes many of these stopover sites and other migratory bird habitat; therefore a comprehensive discussion of migratory birds is not realistic. Below, this discussion provides below, this discussion provides a description of just one species example of many species of migratory birds that use one of the four described land types.. Birds from these groups have different habitat types, are protected under the Migratory Bird Treaty Act, and represent a diversity of migratory bird issues.

D.3.1 Songbird - Cerulean warbler (*Dendroica cerulea*)

Unless otherwise referenced, this description comes from U.S. FWS (2007a).

The cerulean warbler is a FWS Species of Special Concern. During migration, cerulean warblers pass through the southern U.S. and then fly across the Gulf of Mexico to Central America and on to South America (Figure D-2) (Ridgely et al., 2003). Their summer range includes the Appalachian Basin, Gulf Coast, Illinois Basin, and Western Interior coal regions. Much of the core breeding area for the cerulean warbler is located within or near the Appalachian coal region (Figure D-2).

Figure D-2. Cerulean Warbler Habitat and Migratory Path



Cerulean warblers are considered area-sensitive because they prefer breeding in large forested tracts. Cerulean warblers nest and raise young in areas with large tracts of mature deciduous hardwood trees. A diversity of vertical structure in the forest canopy and gaps in the forest canopy, or small forest openings, are desired habitat features. Cerulean warblers nest in uplands, wet bottomlands, moist slopes, and mountains from less than 100 feet to more than 3,500 feet in elevation. During the breeding season, males sing high in mature trees, and females build open-cup nests on the middle and upper branches of deciduous forest trees. Habitats for migratory and winter seasons are not well known but appear to be similar to this warbler's breeding habitat (multiple layers of vegetation in the forest canopy being important characteristics).

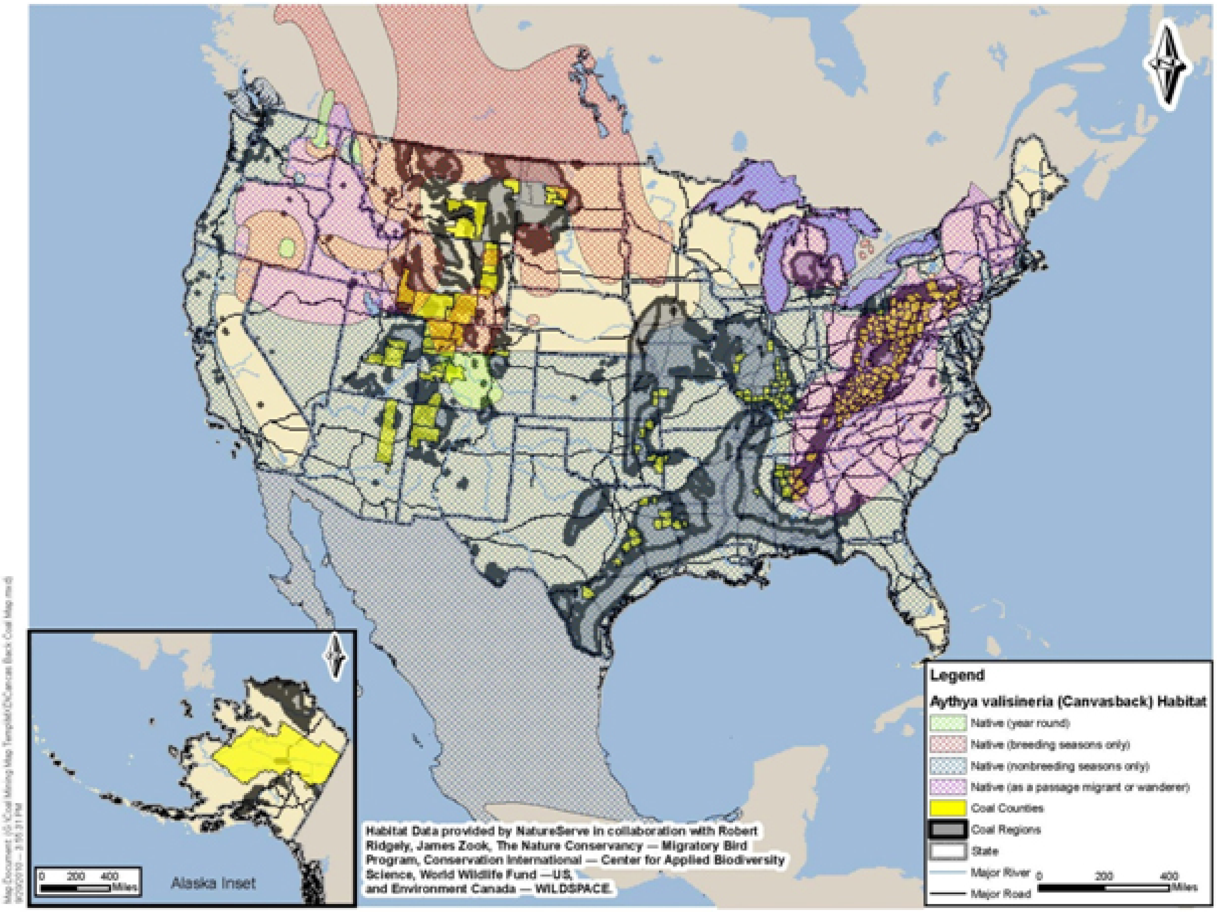
The population of the cerulean warbler has steadily declined at a rate of about three percent per year since 1966. Habitat loss is one of the primary factors contributing to the decrease of the cerulean warbler population. The forests along the Gulf of Mexico used during migration continue to be cleared for coastal development. Within its breeding range, many of the historical forests have been cleared and replaced with farms, cities and suburbs, and many forests tracts that remain are not mature or large enough to support viable populations. Forest management by the removal of the largest trees eliminates the structurally diverse canopy that cerulean warblers prefer, and second-growth stands of similar-sized and relatively young trees do not offer enough structural diversity. Small wooded tracts within a mostly cleared landscape are also unsuitable habitat.

D.3.2 Ground Nester - Mountain plover (*Charadrius montanus*)

The mountain plover is known to occur in Arizona, California, Colorado, Kansas, Montana, Nebraska, Nevada, New Mexico, North Dakota, Oklahoma, South Dakota, Texas, Utah, and Wyoming (Andres and Stone, 2009). The Northern Rocky Mountains and Great Plains, the Colorado Plateau, and the Western Interior coal regions are located within these states. The mountain plover is native during its breeding season in Montana, Wyoming, Colorado, New Mexico, and Texas (Figure D-3) (Ridgely et al., 2003).

The mountain plover is a long distance migrant, and its preferred nesting habitat is relatively specialized, characterized by very short vegetation with significant areas of dry bare ground (e.g., sagebrush/blue gramma habitats in central Montana). Established prairie dog towns offer significant areas of bare ground. The preferred winter habitat of the mountain plover is similar to the nesting habitat: short-grass plains and fields, plowed agricultural fields, sandy deserts, and commercial sod farms. Plovers are also attracted to recent burns (Knopf and Wunder, 2006).

Figure D-3. Mountain Plover (Charadrius montanus) Habitat



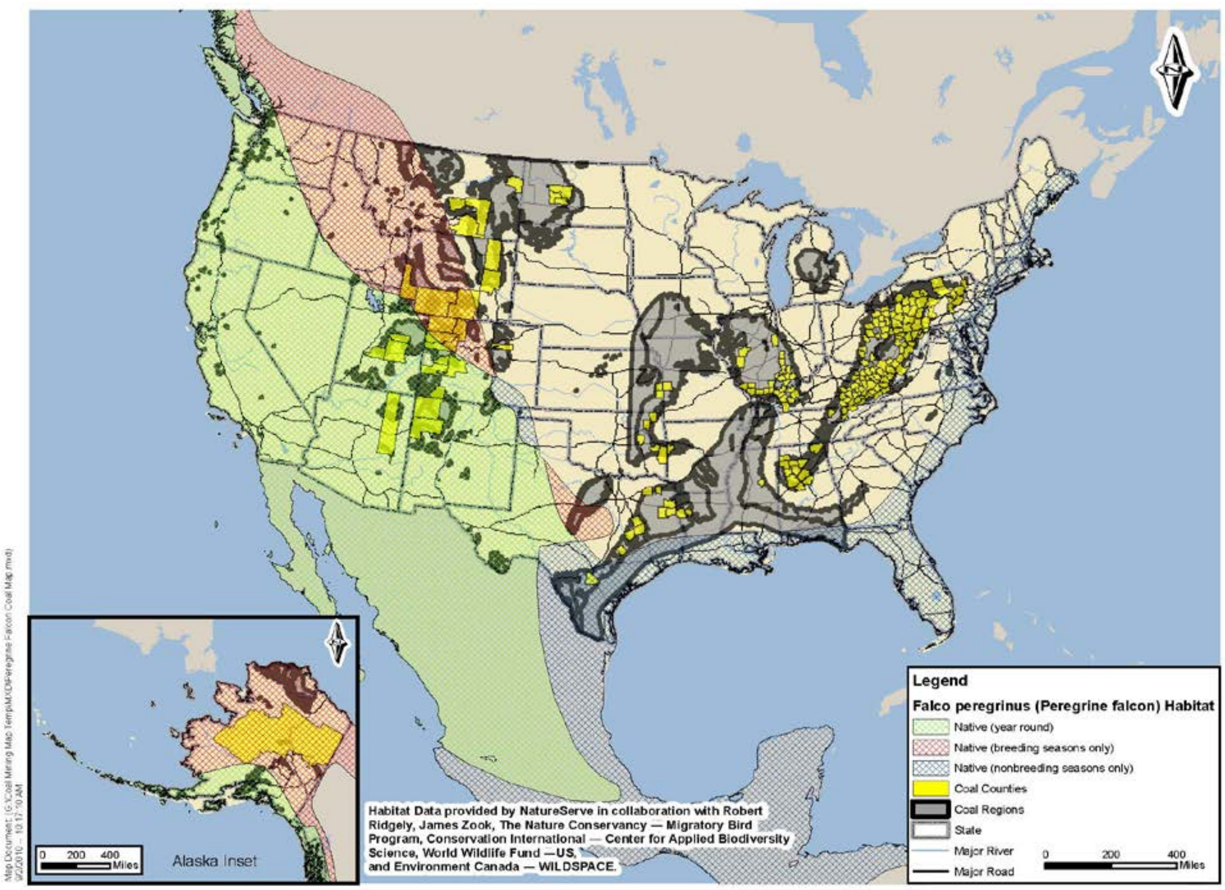
Although there is no chance of restoration to historical population levels due to development of the western Great Plains and California, stewardship habitat management of this species concentrates on maintaining short and sparse vegetation (including the use of grazing), prescribed burning, and protection of prairie dog towns. This type of management will allow for stabilization of the declining population across North America.

An example of stewardship occurs at the Antelope Mine in the Powder River Basin of northeast Wyoming. Surface coal mines have been present in the Powder River Basin since the early 1970s; mines in this area are located within the Northern Rocky Mountains and Great Plains Coal Region and within the Central Migratory Bird Flyway. The Antelope Mine is the only surface mine in that region known to regularly support nesting mountain plovers; nesting pairs have been monitored there annually since 1982 (McKee, 2007). In 2002, the FWS agreed to the restoration of at least 975 acres of mountain plover habitat to mitigate the habitat loss from mining that occurred from 1982 through 2003. Over 20 years of observations have documented that mountain plovers in the vicinity of the mine are most common in black-tailed prairie dog (*Cynomys ludovicianus*) colonies. In 2000, the Antelope Mine proactively initiated a pilot program to establish prairie dogs in reclaimed mining lands to recreate mountain plover habitat. This program was enhanced in 2002 and 2003 to include the construction of artificial colonies in reclamation to support translocated prairie dogs with the purpose of creating mountain plover habitat per the 2002 agreement with the FWS (McKee, 2007).

D.3.3 Raptor - Peregrine falcon (*Falco peregrinus*)

The peregrine falcon was delisted from the Endangered Species List due to recovery in 1999, although it remains listed by some states. The peregrine falcon occurs throughout the continental U.S. (U.S. FWS, 2006b) and, therefore, could be present in all eight coal regions as a native year round (primarily the western U.S.), native during the breeding season (northwestern U.S. and northern Canada), native during the non-breeding (winter) season (Atlantic and Gulf coasts), or as migrants, as reflected in Figure D-4 (Ridgely et al., 2003).

Figure D-4. Peregrine Falcon *(Falco peregrinus)* Habitat



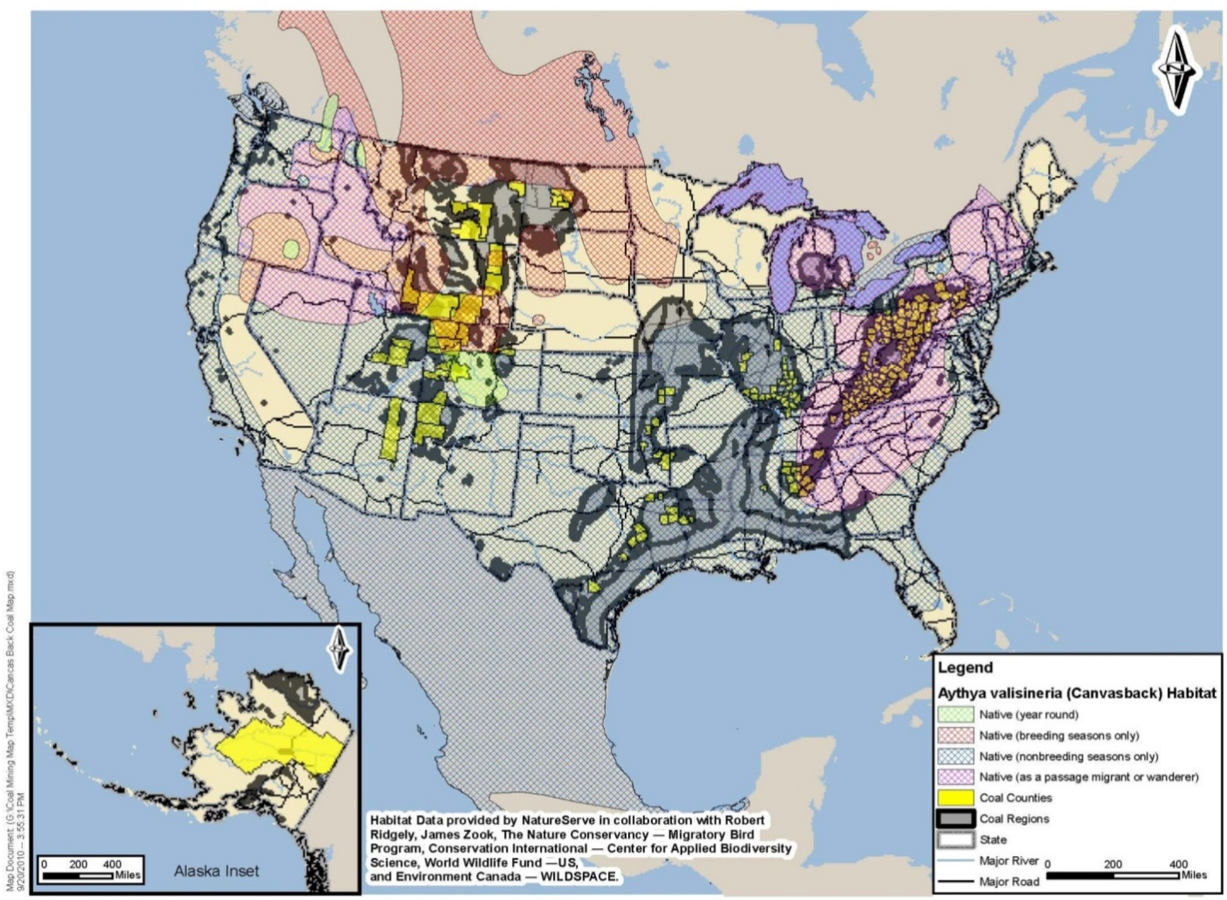
Preferred habitat for the peregrine falcon includes: mountains, forests, tundra, coastlines, and even cities. This bird can live from the tundra to the seacoast, from the high mountains and open forest to the flat savanna. Steep cliffs and rocky ledges are often used as nesting sites. Their nests are shallow scrapes in soil, sometimes taken over from other species. The peregrine wanders widely after the nesting season, regularly following its migrating prey to South America (Alsop III, 2006).

D.3.4 Waterfowl - Canvasback (*Aythya valisineria*)

The canvasback is a duck that uses and is native to areas of the Pacific, Central, and Atlantic flyways. The following U.S. coal regions are located within the flyways traversed by the canvasback for migration: Appalachian Basin, Colorado Plateau, Gulf Coast, Illinois Basin, Northwest, and Western Interior.

The canvasback nests in the prairies of North America, from Minnesota and the Dakotas in the U.S. through Manitoba, Saskatchewan, and Alberta in Canada (Bellrose, 1976; Schroeder, 1984) (Figure D-5) (Ridgely et al., 2003). The prairie wetlands (or potholes) of North America are vital to the canvasbacks, as the open water habitat of this region is its preferred nesting habitat. The female canvasbacks typically occupy floating nests in water six to 24 inches deep, vegetated by bulrush and cattail (Kruse and Takekawa, 1998).

Figure D-5. Canvasback *(Atythya valisineria)* Habitat



As winter approaches and lakes and ponds begin to freeze and harsh weather across the prairies limits food availability, the canvasback migrates to warmer climates using the Pacific Flyway, the Mississippi Flyway, and the Atlantic Flyway. During migration, canvasbacks gather in large groups in the Chesapeake and San Francisco Bays, the Mississippi Delta region and the adjacent Gulf Coast, and interior Mexico (Bellrose, 1976). Twenty five percent of that population uses the Pacific Flyway (Kruse and Takekawa, 1998). Winter habitat for the canvasback in the Mississippi Flyway occurs in the Mississippi River delta and delta lakes in southern Louisiana (Mowbray, 2002). In the Atlantic Flyway, canvasbacks are attracted to flats areas such as the Susquehanna Flats of the Chesapeake Bay. The Susquehanna Flats offer one of the canvasback's preferred food, wild celery.

According to Kruse and Takekawa (1998), the continental population of canvasbacks has fluctuated around 580,000 individuals. A more recent report by the FWS describes the canvasback population in decline, with habitat degradation (wintering, migratory, and summer nesting grounds) the factor with the greatest adverse impact (U.S. FWS, 2011b).

Appendix E. Invasive Species and Noxious Weeds in the Coal States[5]

Over 6,500 nonindigenous species of plants and animals have become established in the U.S. (Williams and Meffee, 1998). Most of these introductions are a result of human activities. They include not only the exotic species that have arrived or been introduced from continents other than North America but also species native to North America that have been introduced to or have colonized locations on the continent outside their native ranges.

Invasive species are a significant threat to natural systems in the U.S. They have adverse economic, environmental, and ecological effects on the habitats and bioregions they invade. While all species compete to survive, invasive species have specific traits or combinations of traits that allow them to out-compete native species. Any non-native species has the ability to become invasive if it can out-compete native species for resources such as nutrients, light, physical space, water, or food. Land clearing and human habitation put significant pressure on local species, and these and other disturbed habitats are prone to invasions that can have adverse effects on local ecosystems and can change ecosystem functions. Disturbed ecosystems may afford invasive species a chance to establish themselves with less competition from native species, which tend to be less adept at competing in these changing ecosystems.

A noxious weed is a term for an invasive plant that is designated and regulated by state and federal laws, such as the federal Plant Protection Act, 7 U.S.C. § 7701 et seq. These noxious weeds are generally detrimental to agriculture, commerce, and/or public health and are recognized as a major threat to ecosystems. Noxious weeds have biological traits that enable them to colonize new areas and successfully out-compete native species. They can transform the structure and function of ecosystems through: direct competition; changes in nutrient cycling, succession, and disturbance regimes; and shifts in evolutionary selection pressures (Mack and D'Antonio, 1998). The spread of noxious weeds threatens the structure and function of many ecosystems worldwide, and certain species have the ability to spread over large areas or acutely threaten an ecosystem over its continental range (Hobbs and Humphries, 1995).

Noxious weeds occur in all states with coal reserves and can be quick to establish on disturbed sites, including land cleared for mining. The following table is a list of federally listed noxious weeds, updated by the U.S. Department of Agriculture on September 30, 2014. Most states also have established their own list of noxious weeds.

[5] This information is provided as background information in support of the discussions contained within the FEIS. Corrections have been made where necessary in response to comments on the DEIS, however OSMRE has not updated this information since publication of the DEIS.

Table E-1. Aquatic Noxious Weeds

Latin Name	Common Name(s)
Azolla pinnata	Mosquito fern, water velvet
Caulerpa taxifolia (Mediterranean strain)	Killer algae
Eichhornia azurea	Anchored waterhyacinth, rooted, waterhyacinth
Hydrilla verticillata	Hydrilla
Hygrophila polysperma	Miramar weed
Ipomoea aquatica	Water-spinach, swamp morning glory
Lagarosiphon major	African elodea
Limnophila sessiliflora	Ambulia
Melaleuca quinquenervia	Broadleaf paper bark tree
Monochoria hastata	Arrowleaf false pickerelweed
Monochoria vaginalis	Heartshape false pickerelweed
Ottelia alismoides	Duck lettuce
Sagittaria sagittifolia	Arrowhead
Salvinia auriculata	Giant salvinia
Salvinia biloba	Giant salvinia
Salvinia herzogii	Giant salvinia
Salvinia molesta	Giant salvinia
Solanum tampicense	Wetland nightshade
Sparganium erectum	Exotic bur-reed
Parasitic Noxious Weeds	**Parasitic Noxious Weeds**
Aeginetia spp.	Varies by species
Alectra spp.	Varies by species
Cuscuta spp.(except for natives)	Dodders
Orobanche spp. (except for natives)	Broomrapes
Striga spp.	Witchweeds
Terrestrial Noxious Weeds	**Terrestrial Noxious Weeds**
Acacia nilotica	Prickly acacia
Ageratina adenophora	Crofton weed
Ageratina riparia	Mistflower, spreading snakeroot
Alternanthera sessilis	Sessile joyweed
Arctotheca calendula	Capeweed
Asphodelus fistulosis	Onionweed
Avena sterilis	Animated oat, wild oat
Carthamus oxyacantha	Wild safflower
Chrysopogon aciculatus	Pilipiliula
Commelina benghalensis	Benghal dayflower
Crupina vulgaris	Common crupina
Digitaria scalarum	African couchgrass, fingergrass
Digitaria velutina	Velvet fingergrass, annual couchgrass
Drymaria arenariodes	Lightning weed
Emex australis	Three-corned jack
Emex spinosa	Devil's thorn
Euphorbia terracina	False caper, Geraldton carnation weed
Galega officinalis	Goatsrue
Heracleum mantegazzianum	Giant hogweed
Imperata brasiliensis	Brazilian satintail
Imperata cylindrica	Cogongrass
Inula britannica	British yellowhead

Latin Name	Common Name(s)
Ischaemum rugosum	Murainograss
Leptochloa chinensis	Asian sprangletop
Lycium ferocissimum	African boxthorn
Lygodium flexuosum	Maidenhair creeper
Lygodium microphyllum	Old world climbing fern
Melastoma malabathricum	Malabar melastome
Mikania cordata	Mile-a-minute
Mikania micrantha	Bittervine
Mimosa invisa	Giant sensitive plant
Mimosa pigra	Catclaw mimosa
Moraea collina	Cape tulip
Moraea flaccida	One leaf cape tulip
Moraea miniata	Two leaf cape tulip
Moraea ochroleuca	Apricot tulip
Moraea pallida	Yellow tulip
Nassella trichotoma	Serrated tussock
Onopordum acaulon	Stemless thistle
Onopordum illyricum	Illyricum thistle
Opuntia aurantiaca	Jointed prickly pear
Oryza longistaminata	Red rice
Oryza punctata	Red rice
Oryza rufipogon	Red rice
Paspalum scrobiculatum	Kodo-millet
Pennisetum clandestinum	Kikuyugrass
Pennisetum macrourum	African feathergrass
Pennisetum pedicellatum	Kyasumagrass
Pennisetum polystachion	Missiongrass, thin napiergrass
Prosopis alpataco	Mesquite
Prosopis argentina	Mesquite
Prosopis articulata	Velvet mesquite
Prosopis burkartii	Mesquite
Prosopis caldenia	Calden
Prosopis calingastana	Cusqui
Prosopis campestris	Mesquite
Prosopis castellanosii	Mesquite
Prosopis denudans	Mesquite
Prosopis elata	Mesquite
Prosopis farcta	Syrian mesquite
Prosopis ferox	Mesquite
Prosopis fiebrigii	Mesquite
Prosopis hassleri	Mesquite
Prosopis humilis	Algaroba
Prosopis kuntzei	Mesquite
Prosopis pallida	Kiawe, algarroba
Prosopis palmeri	Mesquite
Prosopis reptans	Tornillo
Prosopis rojasiana	Mesquite
Prosopis ruizlealii	Mesquite
Prosopis ruscifolia	Mesquite
Prosopis sericantha	Mesquite
Prosopis strombulifera	Argentine screwbean
Prosopis torquata	Mesquite

Latin Name	Common Name(s)
Rottboellia cochinchinensis	Itchgrass
Rubus fruticosis	Wild blackberry
Rubus moluccanus	Wild raspberry
Saccharum spontaneum	Wild sugarcane
Sagittaria sagittifolia	Arrowhead
Salsola vermiculata	Wormleaf salsola
Senecio inaequidens	South African ragwort
Senecio madagascariensis	Fireweed
Setaria pumila ssp. pallidefusca (*Now ssp. subtesselata*)	Cattail grass
Solanum torvum	Turkeyberry
Solanum viarum	Tropical soda apple
Spermacoce alata	Winged false buttonweed
Tridax procumbens	Coat buttons
Urochloa panicoides	Liverseed grass

Appendix F. State and Federally Listed Species from 193 Coal Counties in the U.S.[6]

Table F-1. Species Potentially Affected By These Actions[7]

Category	Common Name	Scientific Name	Federal Status	Coal Basin	Guild
Amphibians	Jemez Mountains salamander	*Plethodon neomexicanus*	LE, CH	CP	Salamanders
Amphibians	Cheat Mountain salamander	*Plethodon nettingi*	LT	AP	Salamanders
Amphibians	Chiricahua leopard Frog	*Lithobates chiricahuensis*	LT,CH	CP	Frogs
Birds	Gunnison sage-grouse	*Centrocurcus minimus*	LT, CH	CP	Grouse
Birds	Southwestern willow flycatcher	*Empidonax traillii extimus*	LE,CH	CP, NRM,	Passerines
Birds	Red-cockaded woodpecker	*Picoides borealis*	LE	AP, G	Woodpeckers
Birds	California condor	*Gymnogyps californianus*	XN	CP	Raptors
Birds	Mexican spotted owl	*Strix occidentalis lucida*	LT,CH	CP, NRM	Raptors
Birds	Piping plover	*Charadrius melodus*	LE,CH	AP, CP, I, NRM,	Shorebird
Birds	Interior least tern	*Sternula antillarum*	LE	CP, G, I, NRM, WI	Shorebird
Birds	Yellow billed cuckoo	*Coccyzus americanus*	LT	CP, NRM	Other
Crustaceans	Illinois cave amphipod	*Gammarus acherondytes*	LE	I	Amphipod
Crustaceans	Kentucky cave shrimp	*Palaemonias ganteri*	LE	I	Freshwater shrimp
Crustaceans	Big Sandy crayfish	*Cambarus callainus*	PE	AP	Crayfish
Crustaceans	Guyandotte River crayfish	*Cambarus veteranus*	PE	AP	Crayfish
Fishes	Diamond darter	*Crystallaria cincotta*	LE, CH	AP, I	Darters
Fishes	Bluemask darter	*Etheostoma akatulo*	LE	AP	Darters
Fishes	Vermilion darter	*Etheostoma chermocki*	LE	AP, WI	Darters
Fishes	Relict darter	*Etheostoma chienense*	LE	G	Darters
Fishes	Watercress darter	*Etheostoma nuchale*	LE	AP	Darters
Fishes	Duskytail darter	*Etheostoma percnurum*	LE	AP	Darters
Fishes	Rush darter	*Etheostoma phytophilum*	LE, CH	AP	Darters
Fishes	Bayou darter	*Etheostoma rubrum*	LT	G	Darters
Fishes	Kentucky arrow darter	*Etheostoma spilotum*	PLT	AP	Darters
Fishes	Cumberland darter	*Etheostoma susanae*	LE, CH	AP	Darters
Fishes	Goldline darter	*Percina aurolineata*	LT,CH	AP	Darters
Fishes	Snail darter	*Percina tanasi*	LT	AP	Darters
Fishes	Yellowfin madtom	*Noturus flavipinnis*	LT,CH	AP	Madtoms

Appendix G. Land Use and Land Covers in the U.S.[8]

G.1 Terrestrial Cover Types of the Appalachian Basin

G.1.1 Oak-Hickory Cover Type

Vegetation. The oak-hickory cover type varies from open to closed woods with a strong to weak understory of shrubs, vines, and herbaceous plants. By definition, oak (Quercus sp.) and hickory (Carya sp.) must make up 50 percent of the stand, singly or in combination. Sweetgum (Liquidambar styraciflua) and red cedar (Juniperus virginiana) are close associates in the southern region of this cover type. Maple (Acer sp.), elm (Ulmus Americana), yellow-poplar (Liriodendron tulipifera), and black walnut (Juglans nigra) often are close associates in eastern and northern parts of the oak forest and the oak-hickory-bluestem mosaic. The major shrubs are blueberry (Vaccinium sp.), Viburnum, dogwood (Cornus sp.), Rhododendron, and sumac (Rhus sp.). The major vines are woodbine (Parthenocissus sp.), grape (Vitis sp.), poison ivy (Rhus radicans), greenbrier (Smilax sp.), and blackberry (Rubus sp.). Important herbaceous plants are sedge (Carex sp.), Panicum, bluestem (Andropogon sp.), Lespedeza, tick clover (Desmodium sp.), goldenrod (Solidago sp.), pussytoes (Antennaria sp.), and Aster; many more are abundant locally. Numerous benefits are provided by the oak-hickory land cover type, including wildlife, timber, watershed protection, recreation, and wilderness and achieving a desirable mix of these benefits requires careful management (Skeen et al., 1993).

Fauna. The fauna of the oak-hickory cover type is similar to that of other eastern hardwood and hardwood-conifer areas and varies somewhat from north to south. Important animals in the cover type include the white-tailed deer *(Odocoileus virginianus)*, black bear (*Ursus americanus*), bobcat *(Felis =(Lynx) rufus)*, gray fox (*Urocyon cinereoargenteus*), raccoon (*Procyon lotor*), gray squirrel *(Sciurus carolinensis)*, fox squirrel (*Sciurus niger)*, eastern chipmunk (*Tamias striatus)*, white-footed mouse (*Peromyscus leucopus)*, pine vole (*Microtus sp.)*, short-tailed shrew (*Blarina brevicauda)*, and cotton mouse (*Peromyscus gossypinus)*.

Bird populations are large. The turkey (*Meleagris gallopavo)*, ruffed grouse (*Bonasa umbellus)*, bobwhite (*Colinus virginianus)*, and mourning dove (*Zenaida macroura)* are game birds in various parts of the cover type. Breeding bird populations average about 225 pairs per 100 acres and include some 24 or 25 species. The most abundant breeding birds include the cardinal (*Cardinalis sp.)*, tufted titmouse (*Parus bicolor)*, wood thrush (*Hylocichla mustelina)*, summer tanager (*Piranga rubra)*, red-eyed vireo (*Vireo olivaceus*), blue-gray gnatcatcher (*Potoptila caerulea)*, hooded warbler (*Wilsonia citrine*), and

[8] This information is provided as background information in support of the discussions contained within the FEIS. Corrections have been made where necessary in response to comments on the DEIS, however OSMRE has not updated this information since publication of the DEIS.

Carolina wren (*Thryothorus ludovicianus)*. The box turtle (*Terrapene sp.)*, common garter snake (*Thamnophis sirtalis)*, and timber rattlesnake (*Crotalus horridus)* are characteristic reptiles.

G.1.1.1 Oak-Pine Cover Type

Vegetation. The Oak-Pine cover type is characterized by forests in which 50 percent or more of the stand is hardwoods, usually upland oaks, but in which southern pines, mainly shortleaf pine (*Pinus echinata)*, make up 25 to 49 percent of the stand. Common associates include sweetgum, hickory, and yellow-poplar.

Fauna. The fauna is similar to that of the adjacent oak-hickory cover type. Animals include the white-tailed deer, fox squirrel, and cottontail (*Sylvilagus sp.)*, and birds include the mourning dove, bobwhite, and turkey. Many small mammals are present, and the avian fauna is quite varied.

G.1.1.2 Maple-Beech-Birch Cover Type

Vegetation. A forest is classified as being of the Maple-Beech-Birch cover type when 50 percent or more of the stand is maple, beech (*Fagus sp.)*, or yellow birch (*Betula alleghaniensis)*, singly or in combination. Common associates include hemlock (*Tsuga sp.)*, elm, basswood (*Tilia Americana)*, and white pine (*Pinus strobes)*. In Virginia and West Virginia, specific species may include: Sugar Maple (*Acer saccharum)*, American Beech (*Fagus grandifolia)*, Yellow Birch, Yellow buckeye (*Aesculus octandra)*, Striped Maple (*Acer pensylvanicum)*, Mountain Maple (*Acer spicatum)*, Smooth Blackberry (*Rubus canadensis)*, and Hobblebush (*Viburnum lantanoides)*.

Herb layers are moderately sparse to moderately dense, with graminoid-rich patches tending to occur on the drier slope convexities (Fleming et al., 2010).

Fauna. The white-tailed deer occurs throughout much of the maple-beech-birch cover type. The hardwood forest and the openings and farms within it provide food and cover for a varied fauna. The black bear is present in many areas. The wolf (*Canis sp.)* is no longer common, but the red fox (*Vulpes vulpes)* and gray fox are rather widespread, as is the bobcat. Several species of squirrels are in the forest, and a number of smaller rodents inhabit the forest floor. The ruffed grouse is widespread, and the bobwhite inhabits the interspersed farmlands and forest openings. Songbirds include the ovenbird (*Seiurus aurocapillus)*, red-eyed vireo (*Vireo olivaceus)*, hermit thrush, scarlet tanager (*Piranga olivacea)*, blue jay (*Cyanocitta cristata)*, black-capped chickadee (*Poecile atricapilla)*, wood pewee (*Contopus virens)*, and magnolia warbler (*Dendroica magnolia)*.

G.1.1.3 Aspen-Birch Cover Type

Vegetation. This cover type is characterized by forest in which 50 percent or more of the stand is aspen (*Populus tremuloides)*, balsam poplar *(Populus balsamifera)*, paper birch *(Betula papyrifera)*, or gray birch *(Betula populifolia)*, singly or in combination. Common associates include maple and balsam fir (*Abies balsamea)*. Other species include *Sassafras*, various maples, and various cherries (*Prunus sp.)* (Fike, 1999).

Fauna. The fauna of the aspen-birch cover type is similar to those of the spruce-fir and white-red-jack pine cover types, with which this cover type is intermingled. The white-tailed deer and black bear are common. The coyote (*Canis latrans)*, bobcat, great horned owl (*Bubo virginianus)*, and other predators feed on a variety of small mammals. The ruffed grouse is present. Among the songbirds are the tufted titmouse (*Parus bicolor)*, blue jay (*Cyanocitta cristata)*, hairy woodpecker (*Picoides villosus)*, downy woodpecker (*Picoides pubescens)*, wood thrush (*Hylocichla mustelina)*, eastern wood pewee (*Contopus virens)*, goldfinch (*Carduelis tristis)*, catbird (*Dumetella carolinensis)*, and red-eyed vireo (*Vireo olivaceous)*.

G.1.1.4 White-Red-Jack Pine Cover Type

Vegetation. Forests in which 50 percent or more of the stand is eastern white pine, red pine, or jack pine, singly or in combination, represent the White-Red-Jack Pine cover type. Common associates include oak, eastern hemlock (*Tsuga Canadensis)*, aspen, birch, northern white-cedar (*Thuja occidentalis)*, and maple.

Fauna. The white-tailed deer and black bear are the most common larger mammals in this cover type, and the moose (*Alces alces)* inhabits the extreme northern portion. The coyote, bobcat, great horned owl, and hawks are among current predators. The snowshoe rabbit (*Lepus americanus)* and other small forest mammals are the main food source of the predators already mentioned. Porcupines (*Hystrix cristata)* inhabit parts of the cover type and become a problem in forest management when they are overly abundant. Breeding bird populations average about 153 pairs per 100 acres. The Blackburnian and black-throated green warblers (*Dendroica fusca* and *Dendroica virens*, respectively) are the most abundant. Other birds include the spruce grouse (*Falcipennis canadensis)*, ruffed grouse, whippoorwill (*Caprimulgus vociferous)*, crested flycatcher (*Myiarchus crinitus)*, wood pewee, white-breasted nuthatch (*Sitta carolinensis)*, veery (*Catharus fuscescens)*, tanagers (*Piranga sp.)*, pileated woodpecker (*Dryocopus pileatus)*, hairy woodpecker, downy woodpecker, blue jay, chickadees, red-eyed vireo, black-and white warbler (*Mniotilta varia)*, ovenbird (*Seiurus aurocapillus)*, redstart (*Setophaga ruticilla)*, black-throated blue warbler (*Dendroica caerulescens)*, hermit thrush, magnolia warbler, Canada warbler (*Wilsonia canadensis)*, yellow-bellied sapsucker *(Sphyrapicus varius)*, olive-sided flycatcher (*Contopus cooperi)*, red-breasted nuthatch (*Sitta Canadensis)*, brown creeper (*Certhia Americana)*, winter wren (*Troglodytes sp.)*, blue-headed vireo (*Vireo solitaries)*, myrtle warbler (*Dendroica coronata)*, slate-colored junco (*Junco hyemalis hyemalis)*, and white-throated sparrow (*Zonotrichia albicollis)*.

G.1.1.5 Loblolly-Shortleaf Pine Cover Type

Vegetation. Loblolly-Shortleaf Pine cover type is characterized by forests in which 50 percent or more of the stand is loblolly pine (*Pinus taeda)*, shortleaf pine (*Pinus edulis)*, or other southern yellow pines (*Pinus palustris)*, singly or in combination. Common associates include oak, hickory, sweetgum, blackgum (*Nyssa sylvatica)*, red maple (*Acer rubra)*, and winged elm (*Ulmus alata)*. The main grasses are bluestems, panicums, and longleaf uniola (*Chasmanthium sessilliflorum)*. Dogwood, viburnum, blueberry, American beautyberry (*Callicarpa Americana)*, yaupon (*Ilex vomitoria)*, and numerous woody vines are common.

Fauna. The fauna varies with the age and stocking of the timber stand, the percentage of deciduous trees, and the proximity to openings, bottom-land forest types, etc. The white-tailed deer is widespread, as is the cottontail. When deciduous trees are present, the fox squirrel is common on uplands. Gray squirrels are found along intersecting drainages. Raccoon and fox are found throughout the cover type and are hunted in many areas.

The eastern wild turkey, bobwhite, and mourning dove are widespread. The most common birds include the pine warbler (*Dendroica pinus)*, cardinal, summer tanager (*Piranga rubra)*, Carolina wren (*Thryothorus ludovicianus)*, ruby-throated hummingbird (*Archilochus colubris)*, blue jay, hooded warbler *(Wilsonia citrine)*, eastern towhee (*Pipilo erythrophthalmus)*, and tufted titmouse.

G.1.2 Terrestrial Cover Types for Colorado Plateau

G.1.2.1 Pinyon-Juniper Cover Type

Vegetation. The name "pygmy forest" characterizes the pinyon pine (*Pinus edulis)* and juniper (*Juniperus sp.)* woodlands of this cover type. The trees occur as dense to open woodland and savanna woodland. Herbaceous production is determined to a large extent by the amount of tree canopy.

Fauna. The major mammalian influents in the pinyon-juniper cover type are mule deer (*Odocoileus hemionus)*, mountain lion (*Puma (Felis) concolor)*, coyote, and bobcat. Elk (*Cervus Canadensis)* are locally important. The less important influents include the wood rat (*Neotoma sp.)*, white-footed mouse (*Peromyscus leucopus)*, cliff chipmunk (*Neotamias dorsalis)*, jackrabbit (*Lepus sp.)*, cottontail, rock squirrel (*Spermophilus sp)*, porcupine, and gray fox. The ring-tailed cat (*Bassariscus astutus)* and spotted skunk (*Spilogale putorius)* occur rarely.

The most abundant resident birds in the pinyon-juniper cover type are the black-billed magpie (*Pica hudsonia*), black-capped chickadee (*Poecile atricapillus*), titmouse, Woodhouse's jay (*Aphelocoma woodhousei)*, western red-tailed hawk (*Buteo jamaicensis)*, golden eagle (*Aquila chrysaetos)*, red-shafted flicker (*Colaptes auratus)*, pinyon jay (*Gymnorhinus cyanocephalus)*, lead-colored bush tit (*Psaltriparus sp.)*, and rock wren (*Salpincttes obsoletus)*. Summer residents include the western chipping sparrow (*Spizella passerine)*, night hawk (*Chordeiles sp)*, black-throated gray warbler (*Dendroica nigrescens)*, northern cliff swallow (*Hirundo sp.)*, western lark sparrow (*Chondestes grammacus)*, Rocky Mountain grosbeak (*Pheucticus melanocephalus)*, desert sparrow (*Passer simplex)*, and western mourning dove. The common winter residents are the pink-sided junco (*Junco hyemalis mearnsi)*, Shufeldt's junco (*Junco hyemalis shufeldti)*, gray-headed junco (*Junco hyemalis caniceps)*, red-backed junco (*Junco hyemalis dorsalis)*, Rocky Mountain nuthatch (*Sitta sp)*, mountain bluebird (*Sialia corrucoides)*, western robin (*Turdus sp)*, and long-crested or Steller's jay (*Cyanocitta stelleri)*. Turkeys are locally abundant during the winter.

Among the common reptiles are the horned lizard (*Phrynosoma sp.)*, sagebrush swift (*Sceloporus graciosus graciosus)*, collared lizard (*Crotaphytus collarix)*, and Great Basin rattlesnake (*Crotalus oreganus lutosus*).

G.1.2.2 Desert Grasslands Cover Type

Vegetation. The grass life form predominates on these plateaus at intermediate elevations, and shrub life forms are dominant at higher and lower elevations. In transition zones, shrubs give way to galleta (*Pleuraphis jamesii)* to black grama (*Bouteloua eriopoda) and* to blue grama (*Bouteloua gracilis)*. Consociations of these species occur, but almost pure stands are the rule. Tobosa replaces galleta in the southern extensions in Texas of this cover type, and three-awn (*Aristida sp.)* becomes the dominant in the northern extensions in Utah. In its northern extensions, this cover type is more open grassland with low shrubs.

Fauna. Pronghorn (*Antilocapra americana)*, or antelope, are the primary larger mammals in the desert grasslands cover type. Mule deer also occur. The coyote and bobcat are among the chief animal predators. They prey on blacktailed jackrabbits (*Lepus californicus)*, cottontails, wood rats, and a large number of small rodent species, such as the kangaroo rat (*Dipodomys deserti)* and the deer mouse (*Peromyscus maniculatus)*. Scaled quail (*Callipepla squamata)* range into the grasslands, especially where brush has made an invasion. Among the smaller birds of the cover type are the horned lark (*Eremophila alpestris*), several sparrows, the loggerhead shrike (*Lanius ludovicianus)*, and nighthawks (Chordellinae). Avian predators include the golden eagle, great horned owl, and various hawks.

G.1.2.3 Ponderosa Pine Cover Type

Vegetation. By definition, ponderosa pine forest is 50 percent or more of one of these pines: ponderosa pine *(Pinus ponderosa)*, Jeffrey pine (*Pinus jeffreyi)*, sugar pine (*Pinus lambertiana)*, limber pine (*Pinus flexilis)*, Arizona ponderosa pine (*Pinus arizonica)*, Apache pine (*Pinus engelmannii)*, or Chihuahua pine (*Pinus leiophylla)*. The exceptions are those situations where western white pine or sugar pine comprises 20 percent or more of the stand; then these species control the name of the forest. This cover type is idealized as open and park-like, with an excellent ground cover of grasses, sedges, and forbs or with an understory of shrubs of low to medium height.

Fauna. In the ponderosa pine cover type, the major mammalian influents are the Rocky Mountain elk (*Cervus Canadensis nelson)*, mule deer, mountain lion, and coyote. Animals of less importance include the bushy-tailed wood rat (*Neotoma cinerea)*, white-footed mouse, bobcat, rock squirrel (*Otospermophilus variegates)*, cottontail, porcupine, mantled ground squirrel (Sciuridae), and chipmunks (Sciuridae).

The most abundant and important resident birds in the ponderosa pine cover type include the pygmy nuthatch (*Sitta pygmaea)*, long-crested jay, sharpshinned hawk (*Accipiter striatus)*, Rocky Mountain nuthatch (*Sitta carolinensis nelsoni)*, mountain chickadee (*Poecile gambeli)*, Cassin's purple finch (*Carpodacus sp)*, redshafted flicker (*Colaptes auratus cafer)*, red-backed junco, western goshawk (*Accipeter atricapillus striatulus)*, and western red-tailed hawk. Birds that are common during the summer include the chestnut-backed bluebird (*Sialia mexicana bairdi)*, Audubon's warbler (*Dendroica coronate auduboni)*, Natalie's sapsucker (*Sphyrapicus thyroids nataliae)*, western chipping sparrow (*Spizella passerine)*, horned owl, and band-tailed pigeon (*Patagioenas fasciata)*.

G.1.2.4 Sagebrush Cover Type

Vegetation. The sagebrush cover type is characterized by shrubs, principally of the genus *Artemisia*, which are usually one to seven feet high. In some situations, other shrubs are part of the vegetation. In other places, grasses such as those of the genera *Agropyron, Festuca, Poa,* and *Bromus*, as well as broadleaved herbs, are found in the understory.

Fauna. Pronghorn use parts of this cover type as rangeland throughout the year, whereas mule deer prefer to use sagebrush rangeland only as winter or transition range. Other wild mammals that are principal inhabitants of this cover type are the Great Basin coyote, black-tailed jackrabbit, pygmy cottontail, Ord's kangaroo rat (*Dipodomys ordii)*, and Great Basin kangaroo rat (*Dipodomys microps)*.

Bird populations are low during the breeding season, averaging only about 25 pairs per 100 acres. The major influent birds include the marsh hawk (*Circus cyaneus)*, red-tailed hawk (*Buteo jamaicensis)*, Swainson's hawk (*Buteo swainsoni)*, golden eagle, bald eagle (*Haliaeetus leucocephalus)*, Cooper's hawk (*Accipeter cooperii)*, prairie falcon (*Falco mexicanus)*, burrowing owl (*Athene cunicularia)*, and long-eared owl (*Asio otus)*. The sage grouse (*Centrocercus urophasianus)* and chukar (*Alectoris chukar)* are important game birds. More than 50 additional species of birds nest within the cover type.

G.1.2.5 Western Hardwoods Cover Type

Vegetation. This cover type is characterized by forests in which 50 percent or more of the stand is hardwood species, except where western white pine, sugar pine, or redwood (*Sequoia sempervirens)* comprises 20 percent or more of the stand (in such cases the cover type is classified as western white pine or redwood). The vegetation is a forest of low to medium tall, broadleaved deciduous or evergreen trees, sometimes with an admixture of low to medium tall needle-leaved evergreens, often with an understory of grass and shrubs.

The widely scattered Rocky Mountain and Plains states "hardwood" portion of the cover type consists primarily of quaking aspen stands with an understory of grasses, forbs, and shrubs. In many places where the aspen stands are inclusions within areas of sagebrush or conifers, they are important sources of food and cover for wildlife. Cottonwood (*Populus sp.)* becomes dominant on plains, more or less replacing aspen, or in riparian corridors

Fauna. An occasional black bear comes down from forests at higher elevations. Mountain lions are no longer numerous; the largest numerous predatory animals are the coyote and the bobcat. The striped skunk (*Mephistis mephistis)* is widespread. Among the more common small mammals are the kangaroo rat, pocket gopher (Geomyidae), and a number of types of mice. Also occurring in this part of this cover type are additional animal species found in the annual grasslands cover type.

Deer are common. The fauna of the aspen portion of the cover type throughout the Rocky Mountain area is essentially that of the adjacent or surrounding cover types, but the aspen stands serve as important areas of food and shelter for many species of wildlife. Where hardwood stands occur on river bottoms in the plains, they are a home for many arboreal and forest-edge species that are not present in the surrounding open country.

The western aspen hardwood forest provides habitat for large numbers of bird species. Over 100 species of songbirds are known to use these forests (DeGraaf et al., 1991). Raptors and avian predators include eagles, falcons, turkey vulture, many species of owl and hawks (DeGraaf et al., 1991). California quail (*Callipepla californica)* are often abundant at lower elevations, and mountain quail (*Oreortyx pictus)* winter at the higher elevations (McNab et al., 2005). Other game birds in these forests include other species of grouse and quail as well as wild turkey (DeGraaf et al., 2005).

G.1.2.6 Douglas-Fir Cover Type

Vegetation. This cover type is characterized by forest consisting of 50 percent or more Douglas fir (*Pseutotsuga menziesii)*, except where redwood, sugar pine, or western white pine comprise 20 percent or more of the stand. Common shrubs in the cover type are of the genera of maple, rock spirea (*Holodiscus dumosus)*, filbert *(Corylus)*, blueberry (*Vaccinium)*, snowberry (*Symphoricarpos albus)*, barberry

(*Berberis sp)*, currant (*Ribes sp.)*, blackberry (*Rubus sp.)*, ninebark (*Physocarpus sp.)*, rose (*Rosa sp.)*, and spirea (*Spiraea sp.)*. Herbage includes grass and other vegetation having a grass-like growth form, especially in the stands in interior states. Here, pinegrass (*Calamagrostis sp.)* and *Carex concinnoides* are present.

Fauna. Common large mammals in this cover type include elk, deer, and black bear. Grizzly bear (*Ursus arctos horribilis)* and moose are in the northern Rockies. Blue and ruffed grouse are present. Most of the northwestern part of the cover type has hawks and owls. Mammalian predators include mountain lions and bobcats. Small mammals include mice, squirrels, marten (*Martes americana)*, chipmunks, and bushy-tailed wood rats (*Neotoma cinerea)*. Some of the more common birds are the chestnut-backed chickadee (*Poecile refescens)*, red-breasted nuthatch, gray jay (*Perisoreus canadensis)*, and Steller's jay.

G.1.2.7 Lodgepole Pine Cover Type

Vegetation. This cover type is characterized by forests in which 50 percent or more of the stand is lodgepole pine (*Pinus contorta)*. Ecologically, lodgepole pine stands are seral to some of the western interior coniferous forests. "Doghair" stands (tree stands of densities greater than those that are optimum for rapid tree growth and shorter rotations) often develop after fires. Understory species, if present, are of about the same genera as found in stands of western larch *(Larix occidentalis), spruce-fir, and interior Douglas fir.*

Fauna. The lodgepole pine cover type has about the same fauna as Douglas-fir, larch, and spruce-fir forests of the same elevational zone. Low productivity of understory flora in many cases limits the number of animals that can be supported. Islands of uncut lodgepole pine provide excellent escape routes and protective refuges or cover for big game animals.

The lodgepole pine forest provides habitat for large numbers of bird species. Over 70 species of songbirds are known to utilize these forests (DeGraaf et al., 1991). Raptors and predators include bald eagles, falcons, turkey vulture, many species of owl, and hawks (DeGraaf et al., 1991). Grouse, mountain quail, doves, and wild turkey are the major game birds (DeGraaf et al., 2005).

G.1.2.8 Fir-Spruce Cover Type

Vegetation. The fir-spruce cover type is characterized by open to dense forests of low to tall needle-leaved evergreen trees and patches of shrubby undergrowth and scattered herbs. Fifty percent or more of the stand is silver fir (*Abies amabilis)*, subalpine fir (*Abies lasiocarpa)*, red fir (*Abies magnifica)*, white fir (*Abies concolor)*, mountain hemlock (*Tsuga mertensiana)*, Engelmann spruce (*Picea engelmannii)*, or blue spruce (*Picea pungens)*, singly or in combination, except where western white pine comprises 20 percent or more of the stand (in which case the cover type would be classified as western white pine). Because of the dense overstory and limited understory, heavily stocked stands are usually not considered a forage resource for domestic livestock unless timber is harvested by patch clearcuts.

Fauna. Seasonally, the fir-spruce cover type and, in particular, the interspersed openings and stream bottoms with broadleaved woody species such as aspen and willows, are used by moose, elk, mule deer, and white-tailed deer. Mountain caribou (*Rangifer tarandus caribou)* originally wintered in Idaho, Washington, and Montana; a few still do. The wolverine (*Gulo gulo)*, lynx, black bear, mountain lion, coyote, and wolf (*Canis lupus)* occur in the cover type. The grizzly bear is present, though in a fraction of its original numbers.

Several species that have been mentioned use the fir-spruce cover type only seasonally, primarily as cover or in following migratory routes. This is the case with the mountain sheep and the mountain goat, which occur more commonly in steep rocky areas. Among the birds in the cover type are several blue grouse and spruce grouse groups, ruffed grouse, and various chickadees, nuthatches, bluebirds, robins, and jays. Among the more common rodents and lagomorphs are the porcupine, beaver, snowshoe hare, squirrels, flying squirrels, pocket gophers, chipmunks, and various species of mice.

G.1.2.9 Alpine Tundra Cover Type

Vegetation. Grasses and grass-like species of rather low stature predominate, but the number of associated forbs is large. Dwarf willows occur in some places on the moist soils of protected slopes and valleys.

Fauna. The pika (*Ochotona sp.)*, pocket gopher, and yellow-bellied marmot (*Marmota flaviventris)* are the only permanent mammalian residents of the alpine cover type. Summer visitors include mule deer, elk, mountain sheep (*Ovis canadensis)*, weasels (*Mustela)*, marten, chipmunks, and the golden-mantled ground squirrel. The only nesting birds are the horned lark, water pipit (*Anthus spinoletta)*, black rosy finch (*Leucosticte atrata)*, rock wren (*Salpinctes obsoletus)*, white-tailed ptarmigan (*Lagopus leucura)*, and robin (*Turdus migratorius)*.

G.1.2.10 Chaparral Mountain Shrub Cover Type

Vegetation. The vegetation of the cover type consists of dense to open brush or low trees. Deciduous, semi-deciduous, and evergreen species are represented. Some of the brush types are so dense that understory vegetation is practically eliminated, while other types support a highly productive understory. Recent activities of man have altered the types of vegetation to such a degree that reconstruction of their original state would be difficult.

Fauna. The fauna is quite diverse from north to south in the chaparral-mountain shrub cover type; however, some species are quite widespread. Mule deer throughout the cover type and white-tailed deer in the south are the most important large mammals. Other large mammals, such as the coyote, mountain lion, bobcat, black-tailed jackrabbit, ringtail, striped skunk, and spotted skunk, are widespread in the cover type. Some important species, such as the javelina and the band-tailed pigeon (*Patagioenas fasciata)*, are found only in the southern part of the cover type. The wood rat is one of the most characteristic animals of the cover type. Other small mammals include ground squirrels and mice.

Birds are very numerous in the brush types of the cover type throughout the year. More than a hundred species were identified in the scrub oak type in Utah. More than 40 resident birds were noted in the oak-juniper community. Among the birds in the oak-juniper areas are the golden-fronted woodpecker (*Melanerpes aurifrons)*, turkey, and bobwhite. Reptile species are quite numerous in the southern portion of the cover type.

G.1.2.11 Desert Shrub Cover Type

Vegetation. The vegetation of the cover type is characterized by xeric shrubs varying in height from four inches to many feet. Stands are generally open, with a large amount of bare soil and desert pavement exposed. Some stands, however, may be relatively dense. Understory vegetation is generally sparse. During years of above-average rainfall, annuals may be conspicuous for a short time.

Fauna. There is a great diversity of habitats in the desert shrub cover type. Consequently, the species of the fauna are quite varied. Dominant animals, however, are characteristically species of rats and pocket mice. In the saltbush-greasewood community, the pale kangaroo mouse (*Microdipodops pallidus)* and little pocket mouse (Perognathus *longimembris)* are common. Animals associated with black sagebrush (*Artemesia nova)* are the desert wood rat (*Neotoma lepida)* and Nuttall's cottontail (*Sylvilagus nuttallii)*. The black-tailed jackrabbit is most numerous in the greasewood (*Sarcobatus sp.)* sites. The cactus mouse (*Peromyscus eremicus)* and desert kangaroo rat (*Dipodomys deserti)* are abundant in the saltbush desert. Merriam's kangaroo rat (*Dipodomys merriami)* is strongly associated with creosotebush. Other important species in the cover type are the long-tailed pocket mouse (*Chaetodipus formosus)* and antelope ground squirrel (*Ammospermophilus sp.)*.

Common larger mammals in the desert shrub cover type are the desert kit fox (*Vulpes macrotis)*, coyote, and western spotted skunk (*Spilogale gracilis)*. Many desert birds are very selective in their type of habitat. Greasewood may furnish a permanent residence for the loggerhead shrike (*Lanius ludovicianus)*. Areas where tall cactus is plentiful furnish homes for many birds, including the Gila woodpecker (*Melanerpes uropygialis)*, several species of owl, and the purple martin (*Progne subis)*. Gambel's quail (*Callipepla gambelii)*, the cactus wren (*Campylorhynchus brunneicapillus)*, and the roadrunner (*Geococcyx californianus)* are common in the southern part of the cover type. Reptiles include numerous species of snakes and lizards, including the Gila monster (*Heloderma suspectum)* of the tall cactus areas.

G.1.3 Terrestrial Cover Types for the Gulf Coast

G.1.3.1 Oak-Hickory Cover Type

A summary of the Oak-Hickory Cover type is described in Appalachian Basin.

G.1.3.2 Oak-Pine Cover Type

A summary of the Oak-Pine Cover type is described in Appalachian Basin.

G.1.3.3 Great Plains Grasslands Cover Type

Vegetation. Short, warm-season grasses predominate in this cover type, and there is a minor interspersion of forbs and shrubs. Vast stretches are dominated almost exclusively by blue grama, buffalo grass being a companion in many areas. The eastern part of the cover type, however, is dominated by grasses of medium stature, such as western wheatgrass (*Pascopyrum smithii)* and needlegrass. The occasional shrubs include juniper, silver sagebrush (*Artemisia cana)*, silver buffalo berry *(Shepherdia argentea)*, and skunk bush sumac (*Rhus trilobata)* in the northern reaches and rabbit brush (*Chrysothamnus sp.)* and mesquite in the southern part. Forbs are generally quite common, but many are ephemerals.

Fauna. Huge herds of American bison once migrated with the seasons across the central plains. Currently, the pronghorn, or antelope, is probably the most abundant large mammal, but mule deer and white-tailed deer are often abundant where brush cover is available, as along stream courses. The white-tailed jackrabbit occupies the northern part of the cover type and the black-tailed jackrabbit can be found in the area south of Nebraska. The desert cottontail is widespread. The lagomorphs, the prairie dogs, and a variety of small rodents are preyed upon by the coyote and a number of other mammalian and avian predators.

Sage grouse, greater prairie chickens, and sharptailed grouse are present in the area. Among the many smaller birds are the horned lark (*Eremophila alpestris)*, lark bunting (*Calamospiza melanocorys)*, and western meadowlark (*Sturnella neglecta)*.

G.1.3.4 Prairie Cover Type

Native cover types in highly altered landscapes can be rare. Prairie cover is one such example.

Vegetation. The prairie cover type is known to many as the tall-grass or true prairie. Bluestem grasses constitute about 70 percent of the vegetation and reach heights of five to six feet in lowland areas. Large numbers of flowering forbs are present but are usually overshadowed by the grasses. Most of the plants are classified as warm-season plants. Woody vegetation is rare. Willow occurs in some places in exceptionally moist areas of the northern part of the cover type, and needle-leaved evergreens and broadleaved deciduous trees are scattered in the southern part. Deciduous trees are common along permanent streams in the eastern portion.

Fauna. Bison (*Bison bison)* once grazed at the western margin of the tall-grass prairie, and the pronghorn, or antelope, is still present there. Jackrabbits are common residents of the prairie, and cottontails are present where there are streams and cover. Burrowing rodents include ground squirrels, prairie dogs (*Cynomys sp)*, pocket gophers, and many smaller rodents. Burrowing predators include the badger (Mustelidae) and the black-footed ferret (*Mustela nigripes)*. The coyote is still common.

The northern portion of the prairie cover type is an important breeding area for a number of species of migrating waterfowl. Many migratory species over-winter on the coastal plains of Texas and Louisiana. Mourning doves have become abundant as shelterbelt plantings have developed. Among the gallinaceous birds, the sharp-tailed grouse, greater prairie chicken (*Tympanuchus cupido)*, and bobwhite (*Colinus virginianus)* are present in fair numbers.

G.1.3.5 Loblolly-Shortleaf Pine Cover Type

A summary of Loblolly-Shortleaf Cover type is described in Appalachian Basin.

G.1.3.6 Oak-Gum-Cypress Cover Type

Vegetation. The vegetation of this cover type varies considerably, but the dominants are of tree life form. It is made up of bottom-land forests in which 50 percent or more of the stand is tupelo, blackgum, sweetgum, oak, and bald cypress, singly or in combination—except where pines comprise 25 to 49 percent of the stand (in which case the cover type is oak-pine). Common associates include willow (*Salix sp.)*, maple, sycamore (*Platanus sp.)*, cottonwood, and beech. Most species are broadleaved deciduous trees. Trees of the mangrove swamp are mainly black mangrove (*Avicennia germinans)* and red mangrove (*Rhizophora mangle)*. The vegetation of the cypress savanna is dominated by needle-leaved deciduous trees and some broadleaved evergreen or deciduous trees and shrubs. The trees and shrubs occur in groves surrounded by open grassland dominated mainly by three-awn species. Mangrove swamps are often flooded by tidewater; the cypress savanna is flooded less frequently and only by fresh water. These forests are important in providing mitigating effects to land use activities in upland areas outside of the forest boundaries (Sharitz and Mitsch, 1993).

Fauna. This cover type is the most fertile and productive of southern habitats for wildlife. In times past, large animals, such as the deer, elk, black bear, mountain lion, bobcat, and wolf, inhabited the forest. Presently, the white-tailed deer is common in most areas. Other mammals include the gray fox, gray squirrel, fox squirrel, raccoon, opossum (*Didelphis virginiana)*, striped skunk, eastern cottontail, swamp rabbit (*Sylvilagus aquaticus)*, and many small rodents and shrews.

Birds include wild turkeys and, in the flooded areas, ibises (Threskiornithidae), cormorants (*Phalacrocorax sp.)*, herons (Ardeidae), egrets (Ardeidae), and kingfishers (Alcedinidae). Common mammals in the mangrove area are the fox squirrel and raccoon. Nesting birds include the mangrove cuckoo (*Coccyzus minor)* and various herons and egrets.

G.1.3.7 Longleaf-Slash Pine Cover Type

Vegetation. This cover type is characterized by forests dominated by longleaf pine (*Pinus palustris)* or slash pine (*Pinus elliottii)*, singly or in combination. Common associates include oak, sweetgum, and southern pines. The main grasses are bluestems, panicums, *Paspalum sp*., and dropseeds (*Sporobolus sp.)*. Saw palmetto (*Serenoa repens)*, gallberry (*Ilex glabra)*, wax myrtle (*Myrica cerifera)*, and sumac (*Rhus sp.)* are important shrubs. (McNab et al., 2005)

Fauna. The fauna varies with the age of the timber stand, and other characteristics. The white-tailed deer is widespread. A variety of small mammals are present including: raccoon, opossum, squirrels, rabbits and small rodents.

The eastern wild turkey and bobwhite are widespread. Migratory waterfowl are present in the area. The American alligator (*Alligator mississippiensis)* is an important reptile.

G.1.3.8 Texas Savanna Cover Type

Vegetation. This is a high-shrub savanna cover type with a dense to very open synusia of broadleaved, deciduous and evergreen low trees and shrubs and needle-leaved, evergreen low trees and shrubs. The grass varies from short to medium tall, and the herbaceous vegetation varies from dense to open. Mesquite is the most widespread woody plant. Others are *Acacia spp.*, oaks, juniper, and ceniza (*Agave colorata)* along the Rio Grande valley and bluffs. *Opuntia* cactus species are widespread. The herbaceous plants are mainly bluestems, three-awns, buffalo grass *(Bouteloua dactyloides)*, gramas, and curly mesquite and tobosa (*Hilaria mutica)* on the Edwards Plateau.

Fauna. The Texas savanna cover type is noted for the abundance of white-tailed deer and wild turkeys. The collared peccary is common in some areas along the Rio Grande, where several species of Mexican or tropical distribution make their only entry into the U.S. (*Tayassu sp.)*. Examples are the chachalaca and the coatimundi. The armadillo (*Dasypus novemcinctus)* is present. The fox squirrel is present in wooded areas along streams. Among the fur bearers are the ringtail and the raccoon.

DeGraaf et al. (2005) summarized birds occurring in Great Plains habitats, including those reported from the East Texas prairies, cross timbers, piney woods and post oak savannah. They report that: a variety of waterfowl are known to use these habitats; major upland game birds are the turkey, bobwhite and various doves; over 100 songbird species are known to utilize these habitats; and a wide variety of raptors and avian predators are found in these habitats including vultures, kite, eagles, numerous species of hawks and owls.

G.1.4 Terrestrial Cover Types of the Illinois Basin

G.1.4.1 Oak-Hickory Cover Type

Vegetation. The oak-hickory cover type varies from open to closed woods with a strong to weak understory of shrubs, vines, and herbaceous plants. By definition, oak and hickory must make up 50 percent of the stand, singly or in combination. The cover type includes multiple vegetation communities, including the Coastal Plain in Alabama and Mississippi, the oak-hickory forest and the mosaic of the oak-hickory forest and bluestem prairie communities of the Ozark Plateaus and interior low plateaus and their extensions, the oak forest of the Appalachians, and the Cross Timbers area of Texas.

Sweetgum and red cedar are close associates in the southern region of the cover type. Maple, elm, yellow-poplar, and black walnut often are close associates in eastern and northern parts of the oak forest and the oak-hickory-bluestem mosaic. The major shrubs are blueberry, viburnum, dogwood, rhododendron, and sumac. The major vines are woodbine, grape, poison ivy, greenbrier, and blackberry. Important herbaceous plants are sedge, panicum, bluestem, lespedeza, tick clover, goldenrod, pussytoes, and aster; many more are abundant locally.

The canopy can be dominated by white oak (*Quercus alba*) and mockernut hickory (*Carya alba*), with pignut hickory (*Carya glabra*) and eastern black oak (*Quercus velutina*). Northern red oak (*Quercus rubra*) may be found in the subcanopy of some examples, particularly on north- and east-facing slopes. The subcanopy may also contain red maple (*Acer rubrum*), sugar maple (*Acer saccharum*), serviceberry (*Amelanchier arborea*), American hornbeam (*Carpinus caroliniana*), blackgum (*Nyssa sylvatica*), and sourwood (*Oxydendrum arboretum*). Hillside blueberry (*Vaccinium pallidum*) may be a prominent low shrub in some examples, along with deerberry (*Vaccinium stamineum*) and maple-leaved viburnum (*Viburnum acerifolium*). The herb dominance may be quite variable depending on aspect. Some other herbs which may be found include slender toothwort (*Cardamine angustata*), wild comfrey (*Cynoglossum virginianum var. virginianum*), and ebony spleenwort (*Asplenium platyneuron*).

Numerous benefits are provided by the oak-hickory land cover type, including wildlife, timber, watershed protection, recreation, and wilderness, and achieving a desirable mix of these benefits requires careful management (Skeen et al., 1993).

Fauna. The fauna of the oak-hickory cover type is similar to that of other eastern hardwood and hardwood-conifer areas and varies somewhat from north to south. Important animals in the cover type include the white-tailed deer, black bear, bobcat, gray fox, raccoon, gray squirrel, fox squirrel, eastern chipmunk, white-footed mouse, pine vole, short-tailed shrew, and cotton mouse.

Bird populations are large. The turkey, ruffed grouse, bobwhite, and mourning dove are game birds in various parts of the cover type. Breeding bird populations average about 225 pairs per 100 acres and include some 24 or 25 species. The most abundant breeding birds include the cardinal, tufted titmouse, wood thrush, summer tanager, red-eyed vireo, blue-gray gnatcatcher, hooded warbler, and Carolina wren. The box turtle and common garter snake are characteristic reptiles.

G.1.4.2 Elm-Ash-Cottonwood Cover Type

Vegetation. The vegetation of this cover type is a tree life form of low to tall broadleaved deciduous trees, varying from open to dense and often accompanied by vines. Cottonwood species usually dominate the cover type and often occur in pure stands. Cottonwood is most common along the streams. Swamp cottonwood (*Populus heterophylla)* is more common in other places. Common associates in the north are willow species and green and white ash (*Fraxinus pennsylvanica and F. Americana)*. Sycamore and sugarberry (*Celtis laevigata)* are common associates in the south. Other common associates are willow, sycamore, beech, and maple. The cottonwood-willow stage is short lived. This stage is followed by the river birch (*Betula nigra)* and silver maple-American elm types in the north and by the sycamore-pecan-American elm or sugarberry-American elm-green ash types in the south.

In Illinois, this cover type includes sugar maple (*Acer saccharinum*), cottonwood (*Populus deltoides*), sycamore (*Platanus occidentalis*), American elm (*Ulmus Americana*), slippery elm (*Ulmus rubra*), black willow (*Salix nigra*), boxelder (*Acer negundo*), river birch (*Betula nigra*), hackberry (*Celtis occidentalis*), and green ash (*Fraxinus pennsylvanica*). Species that may be present in the shrub layer include American beautyberry (*Sambucus Canadensis*) or spicebush (*Lindera benzoin*). Woody and herbaceous vines can be prominent, including, among the woody vines, Virginia creeper (*Parthenocissus quinquefolia*) and riverbank grape (*Vitis riparia*). Herbaceous vines species include groundnut (*Apios americana*), American hogpeanut (*Amphicarpaea bracteata*), and wild cucumber (*Echinocystis lobata*). Herbaceous grasses, forbs, and ferns dominate the ground layer, including calico aster (*Symphyotrichum lateriflorum*), false nettle (*Boehmeria cylindrical*), Virginia wildrye (*Elymus virginicus*), pale touch-me-not (*Impatiens pallida*), Canadian woodnettle (*Laportea canadensis*), ostrich fern (*Matteuccia struthiopteris*), sensitive fern (*Onoclea sensibilis*), Canadian clearweed (*Pilea pumila*), and stinging nettle (*Urtica dioica*) (Faber-Langendoen, 2001).

Fauna. Because this cover type is far flung and is in the main flood plains of rivers dissecting a number of other, quite different cover types, the fauna is varied and, in many cases, influent from the surrounding cover types. Forest-edge animals and birds are common, and numerous ones include the cottontail, bobwhite, white-tailed deer, raccoon, red fox, coyote, striped skunk, spotted skunk, meadow jumping mouse (*Zapus hudsonius)*, fox squirrel, and ground squirrels. Other birds include the catbird (*Dumetella carolinensis)*, goldfinch (*Spinus tristis)*, yellow-billed cuckoo (*Coccyzus americanus)*, indigo bunting (*Passerina cyanea)*, cardinal, lark sparrow (*Chondestes grammacus)*, mockingbird (*Mimus polyglottos)*, common crow (*Corvus brachyrhunchos)*, blue jay, robin, ruby-throated hummingbird, ruffed grouse and Cooper's hawk.

G.1.4.3 Oak-Pine Cover Type

A summary of the Oak-Pine Cover type is included under the Appalachian Basin.

G.1.4.4 Maple-Beech-Birch Cover Type

A summary of the Maple-Beech-Birch Cover type is included under the Appalachian Basin.

G.1.4.5 Aspen-Birch Cover Type

A summary of the Aspen-Birch Cover type is included above in the Appalachian region.

G.1.4.6 Prairie Cover Type

A summary of the Prairie Cover type is included above in Northern Rocky Mountains and Great Plains.

G.1.4.7 Oak-Gum-Cypress Cover Type

A summary of the Oak-Gum-Cypress Cover type is included in Gulf Coast.

G.1.4.8 Agriculture Cover Type

The agriculture cover type includes land used mainly for production of food crops, such as wheat, corn, soybeans, or commodities such as cotton. This cover type is not restricted to a particular climate, physiography, or soils, but occurs where economic conditions are favorable. The best examples of this type are the former prairies of the Midwestern U.S., which have been replaced with corn and wheat, the Central Valley of California where vegetable crops are grown, and the Mississippi basin where soybeans and other agricultural crops are produced. In other areas, the agriculture cover type is intermixed with natural cover, which provides an idea of natural vegetation that is characteristic of the section.

G.1.5 Terrestrial Cover Types for Northern Rocky Mountains and Great Plains

G.1.5.1 Mountain Grasslands Cover Type

Vegetation. Although the mountain grasslands cover type ranges from foothills at northerly latitudes to high mountain sites, it is characterized throughout by bunchgrasses of the fescue and wheatgrass groups.

Fauna. In the foothills portion of the mountain grasslands cover type, pronghorn, or antelope, are resident and mule deer are winter visitors. Where there is an interface with the sagebrush cover type, common animals are the black-tailed jackrabbit, pygmy cottontail, and various mice. At low to medium elevations, various subspecies of ground squirrels are present, as well as the badger. At medium to high elevations, the grasslands seasonally support Rocky Mountain elk and mule deer. The pocket gopher is well distributed throughout the cover type. Predators, which are well distributed at high elevations, are the bobcat, black bear, and coyote. Two of the more common birds present are the robin and horned lark. Marsh hawks, sparrow hawks, and golden eagles are common raptors.

G.1.5.2 Aspen-Birch Cover Type

A discussion of the Aspen-Birch Cover type is provided above in the Appalachian Region.

G.1.5.3 Prairie Cover Type

Vegetation. The prairie cover type is known to many as the tall-grass or true prairie. Bluestems constitute about 70 percent of the vegetation and reach heights of five to six feet in lowland areas. Large numbers of flowering forbs are present but are usually overshadowed by the grasses. Most of the plants are classified as warm-season plants. Woody vegetation is rare. Willow occurs in some places in exceptionally moist areas of the northern part of the cover type, and needleleaved evergreens and broadleaved deciduous trees are scattered in the southern part. Deciduous trees are common along permanent streams.

Fauna. Bison once grazed at the western margin of the tall-grass prairie, and the pronghorn, is still present there. Jackrabbits are common residents of the prairie, and cottontails are present where there are streams and cover. Burrowing rodents include ground squirrels, prairie dogs, pocket gophers, and many smaller rodents. Burrowing predators include the badger. The coyote is still common.

The northern portion of the prairie cover type is an important breeding area for a number of species of migrating waterfowl. Mourning doves have become abundant as shelterbelt plantings have developed. Among the gallinaceous birds, the sharp-tailed grouse, greater prairie chicken, and bobwhite are present in fair numbers.

A description of the Chaparral Mountain Shrub cover type is provided in Colorado Plateau.

G.1.5.13 Desert Shrub Cover Type

A description of the Desert Shrub cover type is provided in Colorado Plateau.

G.1.6 Terrestrial Resources for Northwest Basin

G.1.6.1 Cover Types in the Alaska Range Humid Tayga-Tundry-Meadow and Coastal Humid Tayga-Meadow Provinces

Vegetation. Vertical vegetational zonation characterizes the Alaska Range and Wrangell Mountains, beginning with dense bottom-land stands of white spruce and cottonwood on the floodplains and low terraces of the Copper and Susitna Rivers. Above the terraces, poorly drained areas up to 1,000 feet support stands of black spruce. Upland spruce-hardwood forests of white spruce, birch, aspen, and poplar, with an undergrowth of moss, fern, grass, and berry, extend to timberline at about 2,500 to 3,500 feet. Tundra systems of low shrubs and herbaceous plants form discontinuous mats among the rocks and rubble above timberline. White mountain-avens may cover entire ridges in the Alaska Range, associated with moss campion, black oxytrope, arctic sandwort, lichens, grasses, and sedges. These tundra systems stop short of the permanent ice caps on the highest peaks.

Throughout the Cook Inlet lowlands, lowland spruce-hardwood forests are abundant. Bottom land spruce-poplar forest adjoins the larger river drainages, along with thickets of alder and willow. Wet tundra communities exist along the Cook Inlet coastline. The Copper River lowland is characterized by black spruce forest interspersed with large areas of brushy tundra. White spruce forests occur on south-facing gravelly moraines, and cottonwood-tall bush communities are common on large floodplains.

Fauna. Caribou and introduced bison inhabit the area, and Dall sheep (*Ovis dalli)* are found in the high mountains. Moose (*Alces alces*), brown bear (*Ursus arctos*), and black bear (*Ursus americanus*) are common to the area. Upland furbearers, such as marten (*Martes americana)*, mink (*Neovison vison)*, and shorttail (*Mustela ermine)* and least weasels (*Mustela nivalis)*, are common. Hoary marmots (*Marmota caligata)* populate mountainous areas, and woodchucks *(Marmota monax)* are found in the lower open woodlands. There is prime habitat for arctic ground squirrels *(Spermophilus parryii)* and northern flying squirrels (*Glaucomys sabrinus)*. The range of the longtail (*Microtus longicaudus)* and yellow-cheeked (*M. xanthognathus)* voles in interior Alaska corresponds closely to this region.

Appendix K. Summary of Public Comments Received on Draft Environmental Impact Statement

This Appendix contains written comments received during the public comment period for the Draft Environmental Impact Statement (DEIS) for the Stream Protection Rule. On July 16, 2015, OSMRE announced that the Proposed Rule, DEIS, and Draft Regulatory Impact Analysis (RIA) were available for review at www.regulations.gov, at www.osmre.gov, and at selected OSMRE offices. On July 17, 2015, OSMRE published a notice in the Federal Register announcing the availability of the DEIS for the proposed rule, see 80 FR 42535-42536. The notice reiterated that the DEIS was available for review at www.regulations.gov, www.osmre.gov, and the OSMRE offices listed in the notice. The comment period for the DEIS was originally scheduled to close on September 15, 2015.

On July 27, 2015, OSMRE published the Proposed Stream Protection Rule in the Federal Register, see 80 FR 44436-44698. That document reiterated that the Proposed Rule, DEIS, and Draft RIA were available for review at www.regulations.gov, www.osmre.gov, and the OSMRE offices listed in the notice. The comment period for the Proposed Rule and Draft RIA was originally scheduled to close on September 25, 2015. In response to requests for additional time to review and prepare comments on all three documents, OSMRE extended the comment period for the proposed rule, DEIS, and Draft RIA through October 26, 2015, see 80 FR 54590-54591 (Sept. 10, 2015).

Interested parties, therefore, received a total of 102 days to review the proposed rule and supporting documents. During that time, OSMRE also held six public hearings in Colorado, Kentucky, Missouri, Pennsylvania, Virginia, and West Virginia. OSMRE received approximately 95,000 comments from all sources on the Proposed Rule, DEIS, and Draft RIA.

In accordance with the National Environmental Policy Act (NEPA), public and agency written comments were reviewed and incorporated into this Final Environmental Impact Statement (FEIS). These public and agency comments were taken into consideration by OSMRE in preparing the FEIS as well as in its decision making process.

K.1 Comment Receipt and Review

K.1.1 Comment Receipt

Comments on the DEIS included written correspondence received during the 102-day public comment period. All comments received during that period are included in Section K.3 of this Appendix.

K.1.2 Comment Review

In accordance with 40 CFR 1503.4, comments were assessed and considered as follows:

- Each written comment was assigned an identification number. Comment letters were numbered sequentially based on when they were received by OSMRE.
- Each written comment was reviewed carefully. Within each comment, substantive comments were identified and assigned into a category based on topic area within the EIS.
- The identified comments were reviewed and responded to by OSMRE. The table of individual comments and detailed responses is provided in Section K.3 of this Appendix.
- There were some comments that were made frequently enough that OSMRE prepared "Master Responses" to these comments. Those comments and their responses provided in Section K.2 of this Appendix.
- The individual substantive comments were assigned a number and a response developed for each comment.

K.1.3 Locating Your Comments

Section K.4 lists commenters' names alphabetically followed by the comment number.

K.2 Master Responses to Public Comments on the Stream Protection Rule (SPR) DEIS September 20, 2016

OSMRE prepared Master Responses for comments that were made frequently. . The following is a list of the Master Response topics:

- NEPA Compliance
- Alternatives
- Cooperating Agency Involvement
- Compliance with Statutory Requirements and Regulations
- Regulatory and Energy Market Baseline for Analysis
- Technical Accuracy
- Water Quality Benefits
- Monetizing Environmental Benefits
- Public Health Effects
- Model Mines Analysis
- Material Damage to the Hydrologic Balance
- Stranded Reserves
- Industry Operational Costs
- Regulatory Authority Costs
- Industry Administrative Costs
- Alternative Analysis Provided by the National Mining Association
- Employment Effects and Multipliers
- Tax Effects

1. NEPA Compliance

Comment: Several commenters stated that the DEIS did not comply with regulations for conducting analyses under the NEPA. Some commenters stated that OSMRE failed to adopt the basic impact analysis and mitigation strategy hierarchy as required by NEPA or a basic scientific approach to the evaluation of environmental impacts associated with each of the different Alternatives. One commenter stated that the DEIS did not provide a predictive analysis in sufficient detail to ascertain the nature, magnitude, duration (timing), extent (geographic distribution), level of confidence, and range of uncertainty of the predicted changes. Commenters also stated that OSMRE's effects analysis methodology was not rigorous enough and did not fully incorporate the "best available science." One commenter states that the ability of the environment to recover, or rebound, was largely ignored in the DEIS. Commenters stated that the OSMRE was incomplete in its identification of past, present, and reasonably foreseeable actions that regulate, or that will indirectly impact, the coal mining industry. Furthermore, these commenters stated that OSMRE had not sufficiently evaluated the cumulative impacts of these regulations.

Response: The FEIS meets or exceeds requirements for conducting analyses under NEPA. As described in section 4.0.1 in the FEIS, NEPA requires analysis of three categories of effects; direct, indirect and cumulative. Direct Effects are effects that are caused by the action and which occur at the same time and place; indirect effects are effects that are caused by the action but which occur later in time or farther removed in space, but which are still reasonably foreseeable; and cumulative effects are the impacts on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (federal or non-federal) or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time. The analysis of the full suite of economic, environmental, and social impacts of the project are addressed in Chapter 4 of the FEIS. In accordance with NEPA regulations, both the direct and indirect effects of the Alternatives, as well as the cumulative effects, are provided in the FEIS. The effects of individual and collective Alternative rule elements (e.g. approximate original contour, stream restoration, etc.) on surrounding ecosystems, resources, and future coal production were compared to practices under the No Action Alternative, were used to determine the direct and indirect impacts of the Action Alternatives. Impacts to mineral resources, geology, soils, topography, water resources, air quality and greenhouse gas emissions, land use, biological resources, wetlands, recreation, visual resources, utilities and infrastructure, noise, cultural resources, and socioeconomics (among others), are presented in Chapter 4 of the FEIS. Each section in Chapter 4 includes a discussion of the effects of the current regulatory environment for that resource under the No Action Alternatives, the environmental consequences of the Proposed Action and alternatives on that resource, and, where adverse impacts of the action on the resource is anticipated, consideration of potential mitigation options for identified adverse effects. In response to public comment, we have added text to section 4.0 and individual resource sections in the FEIS that more clearly articulates the criteria for impacts used in this analysis. Please refer to specific chapter sections for details on these analyses.

OSMRE fully considered the potential cumulative impacts of the Proposed Action. The cumulative impact analysis in section 4.5 considers the effects of past, present, and reasonably foreseeable future actions on the environmental resources within the study area, including those that affect multiple resources. To evaluate the cumulative impacts of the proposed rule, we identified the spatial and temporal boundaries for the consideration of each resource, and then addressed the impacts of past, present, and reasonably foreseeable future actions in order to characterize potential cumulative impacts. We determined spatial boundaries by considering where impacts to a given resources would no longer be affected or where effects were no longer significant, which was at the coal region level. For the temporal extent, we considered relevant past, present, and expected rulemaking that did not require significant speculation. Several other recent regulatory changes have been added to the cumulative impacts analysis in the FEIS.

The methodologies for our analyses are included in the FEIS and we have used the best relevant and contemporary science and data to conduct our analyses on the proposed rule and the Action Alternativesin accordance to this standard. We have also identified uncertainties and data gaps where they exist. All of these analyses supporting the FEIS were developed in accordance with 43 CFR Part 46, which contain DOI's regulations for implementing NEPA, and we have appropriately addressed the aforementioned framework for both environmental and socioeconomic conditions resulting from the Action Alternatives.

2. Alternatives

Comment: OSMRE received numerous comments regarding the alternatives that were considered in the DEIS. The overlying theme to these comments was that OSMRE had not considered the full range of reasonable alternatives as required under NEPA.

Some commenters provided numerous suggestions for other alternatives to consider, and other comments criticized the alternatives we analyzed as being too similar to each other or as not realistic or implementable for reasons they elaborated on in the comment (see the table of comments to for further details). Another commenter expressed concern that the alternatives we considered in the DEIS were vastly different than the possible alternatives OSMRE mentioned within the Notice of Intent (NOI).

As mentioned above, we received several comments stating that the alternatives were too similar and did not capture the true range of alternatives to achieve OSMRE's rulemaking goals. For example, one commenter stated that additional alternatives should have been considered to examine other combinations of the various rule elements. This commenter expressed concern that the alternatives were too similar to each other because several requirements, such as baseline data collection, are the same across most of the Action Alternatives. Another commenter expressed that there were other possible options for achieving the minimization of impacts than the ones we considered. This comment specifically posited that OSMRE should have addressed additional alternatives regarding mining through streams with and without the requirement for buffers. Another comment noted that there are differences between the alternatives in "width of the stream buffers, differences in the definition of stream types, and variable allowances for mining through streams, mountaintop mining, and placement of materials in valley bottoms" but still felt that the variability between alternatives was insufficient to represent a reasonable range of alternatives. This same commenter felt that the alternatives analyzed were too similar because requirements for the salvage and redistribution of organic materials and requirements related to revegetation were the same across most of the alternatives.

Some comments offered other possibilities for requirements and allowances within the proposed regulations as alternatives that we should consider. For example one comment suggested that we analyze a new alternative that would include the following: allowing for mining in streams conducted in progressive stages with progressive restoration, allowing changes in hydrology (i.e. not considering a hydrologic change as material damage to the hydrologic balance outside the permit area), and allowing reclaimed sites to deviate from the approximate original contours.

A commenter also expressed the concern that there should be an alternative based on stronger enforcement of the existing rules, while another comment proposed that there should be an alternative based on greater interaction between OSMRE and other federal and state agencies with jurisdiction over the Clean Water Act (CWA) and the Endangered Species Act (ESA). Similarly we received comments stating that we should not allow impacts to coal production to influence our decision on whether an alternative is reasonable. Commenters opined that coal production impacts should not determine whether an alternative is reasonable because the societal and environmental costs of coal production are not fully acknowledged or captured, and that therefore the benefits of more protective alternatives may be greater than we currently realize. These same commenters also argued that relying on coal production impacts was misleading because they anticipate that coal production will continue to decline further from other factors independent of our rulemaking. The commenters alleged that OSMRE has acted in an arbitrary and capricious manner by in dismissing these alternatives, claiming that we overlooked relevant and important considerations that support adoption of a more protective alternative.

Still others expressed the concern that some of the alternatives we considered were not implementable because they contained requirements that contradicted SMCRA and therefore that OSMRE could not consider such alternatives as being "reasonable" under NEPA.

And finally, one commenter expressed objection to consideration of the 2008 Stream Buffer Zone rule in Alternative 9. The U.S. District Court for the District of Columbia vacated the 2008 stream buffer zone rule on February 20, 2014, in National Parks Conservation Ass'n v. Jewell, 2014 U.S. Dist. LEXIS 152383 (D.D.C. Feb. 20, 2014). See also 79 FR 76227–76233 (Dec. 22, 2014).

Response: Regarding the alternatives mentioned as possibilities for consideration within the NOI, the comment is accurate that the NOI proposed alternatives and that these alternatives were not identical to the alternatives considered in the EIS. The NOI is published very early in the process, even before the scoping process is conducted, in compliance with 40 CFR 1501.7. The scoping process provides, among other things, the opportunity for participants to identify concerns, potential impacts and relevant effects of past actions and possible alternative actions. Scoping is therefore done very early in the process before extensive discussion, analysis or deliberations of the results have occurred; it is therefore a natural and expected outcome of the NEPA process that the Proposed Action and alternatives would change following the early identification of possible alternatives provided at scoping. As explained in the Department of Interior regulations for implementing NEPA, the input received during scoping efforts is important to help define the issues for consideration. However, suggestions obtained during scoping are not binding but are only important options for the lead agency to consider (43 CFR 46.235(b)). OSMRE refined the alternatives in response to internal agency deliberations, cooperating agency input, and consideration of public comments received during scoping. As the lead agency OSMRE is ultimately responsible for determining the scope and content of the environmental impact statement.

OSMRE considered a reasonable range of alternatives that reflect the purpose and need for the stream protection rule and has not changed the alternatives considered in the DEIS. The FEIS maintains these alternatives as the study alternatives, but also incorporates some minor revisions to the Preferred

Alternative (Alternative 8) based on comments received on the DEIS and RIA. Regarding the comments on similarity of the alternatives considered, the Council on Environmental Quality (CEQ) has provided guidance to agencies on what constitutes a range of reasonable alternatives when there are an infinite number of possible alternatives. See question 1b. in CEQ's Forty Most Asked Questions Concerning CEQ's National Environmental Policy Act Regulations. The guidance states that where there may exist a very large or even an infinite number of possible reasonable alternatives, the agency may limit the alternatives analyzed to a reasonable number so long as they cover the full spectrum of alternatives. In the case of regulatory revisions, a "full spectrum of alternatives" would be one that encompasses alternatives that range from a major revision of the existing regulations to an alternative on the other end of the spectrum that changes nothing (i.e. the No Action Alternative). OSMRE has opted to analyze alternatives based on differing combinations of the individual requirements; the alternatives we have chosen to analyze differ from each other in the sum total of their requirements even if they do not differ from each other on one or more of the individual requirements. Within the nine alternatives that we identified for detailed anlaysis, the alternatives range from an alternative that changes none of our regulations under SMCRA (the No Action Alternative) to one that would represent a major change of our regulations under SMCRA (Alternative 2). Alternative 2 would prohibit mining operations in or through perennial streams, prohibit placement of excess spoil intermittent or perennial streams, and prohibit variances from AOC, all without exception. The seven other alternatives fall between these two ends of the spectrum and include varying combinations of changes in the specific proposed rule components.

The chosen alternatives do not consider every possible combination of various rule elements because such an analysis is not required by NEPA, and would be impracticable due to the number of possible scenarios. Additionally, the various combinations of rule components are bounded by the need to be reasonable and to achieve the purpose of environmental protection. If we were required to consider a different scenario for each of the components of the proposed rule against every other possible combination of scenarios the number of potential alternatives, the burden on the agency would be unreasonable. Therefore, we limited the number of action alternatives by only considering alternatives that represent combinations of rule components that achieve the purpose and need and do not, through any specific component or combination of rule component, contradict sound science. We do not need, for example, to address a suite of alternatives that would analyze multiple scenarios for how long an applicant must collect baseline against a suite of alternatives with varying buffer widths because to create alternatives in this way would create an excessively large number of alternatives, and because cost and data quality needs dictate what is reasonable to require for baseline data collection.

Regarding the idea of an alternative based on stronger enforcement of existing rules, OSMRE disagrees that this is a separate alternative from the no action alternative. The implementing regulations for SMCRA already contain mechanisms to provide for enforcement of existing regulations including those that provide the regulatory authority the ability to cite an operator for violation of permit conditions, including violation of permit conditions driven by CWA and ESA requirements. The implementing regulations of SMCRA also contain mechanisms for OSMRE to assess state SMCRA program compliance with the federal regulations and to require corrections of deficiencies where they exist or to alternatively bring the program for that state back under direct federal control.

Additionally, direct enforcement of the requirements of the ESA and the CWA is not within the authority of the SMCRA regulatory authority except to the extent that these requirements are captured within the permit conditions. Our existing regulations already require compliance with all conditions of the permit. Under the Action Alternatives we are proposing to revise our regulations to require demonstration of compliance with the ESA before the SMCRA regulatory authority issues the permit; this revision does not change existing requirements under the ESA but within our regulations would clarify an important point regarding when the consultation (if one is necessary) must be initiated and completed.

Greater interaction between the SMCRA regulatory authority and other federal and state agencies is definitely to be encouraged. However, a separate alternative based solely on a greater degree of interaction is not warranted. All of the Action Alternatives with the exception of Alternative 9 contain requirements that will promote or require greater interaction. For example, each alternative other than the No Action Alternative and Alternative 9 would require the applicant to include information on the hydrology, geology, and aquatic biology of the proposed permit area and the adjacent area, including 12-months of baseline data on surface waters and aquatic biologic resources. Sampling methods for determining the biologic condition of streams must be established or endorsed by the agency responsible for implementing the Clean Water Act, 33 U.S.C. § 1251 et seq.; coordination on methodologies provides another point of interaction. Additionally these alternatives would also require that the regulatory authority provide the protection and enhancement plan and the baseline resource information submitted under § 779.20 to the appropriate regional or field office of the U.S. Fish and Wildlife Service or the National Marine Fisheries Service, as applicable, whenever the resource information submitted under § 779.20 of this chapter includes species listed as threatened or endangered under the Endangered Species Act of 1973, 16 U.S.C. § 1531 et seq., designated critical habitat under that law, or species proposed for listing as threatened or endangered under that law. Thus, the Action Alternatives provide both a window of time and new requirements that would allow for and produce greater interaction.

Regarding the concern that OSMRE should not dismiss alternatives based on impacts to coal production, we must also disagree. Carrying forward alternatives without consideration of their impact on coal production would not be consistent with Congress's intent as described in the statement of purpose for SMCRA. See 30 U.S.C. § 1202. OSMRE dismissed some alternatives based on untenable impacts to production (see Section 2.6 of the DEIS), but retained others for analysis that had more balanced impacts on production in comparison to the environmental benefits expected. The Regulatory Impact Analysis (RIA) provides the information needed to consider the costs and benefits of the regulatory alternatives as required under Executive Order 12866 Regulatory Planning and Review (1993, as amended by Executive Order 13563 (2011).

Similarly OSMRE has not eliminated Alternative 2 despite the comment that correctly stated that "Alternative 2 would effectively prohibit all mountaintop removal operations and all variances. SMCRA specifically authorizes an AOC variance for mountaintop removal and steep slope mining; therefore OSMRE cannot eliminate mountaintop removal or steep slope operations without an amendment to SMCRA." In 1981, the Council addressed the question in its document, "Forty Most Asked Questions Concerning CEQ's National Environmental Policy Act Regulations". See 46 FR 18026 (1981). The response to question 2b. clarifies that agencies preparing an EIS must consider reasonable alternatives, including those that are outside the scope of what Congress has currently approved or funded. This requirement exists because the analysis of these alternatives may serve as the basis for identifying a need for Congressional action, in this case to amend SMCRA.

Finally, OSMRE also disagrees with the comment that Alternative 9 is invalid because it consists of the vacated 2008 stream buffer zone rule. The U.S. District Court for the District of Columbia vacated the 2008 stream buffer zone rule based on procedural issues and not on the merits of specific requirements contained within the rule. Specifically, the court ordered the 2008 Stream Buffer Zone rule on February 20, 2014, because ‘‘OSM’s determination that the revisions to the stream protection rule encompassed by the 2008 Rule would have no effect on threatened and endangered species or critical habitat was not a rational conclusion’’ and that therefore our failure to initiate consultation on the 2008 rule was a violation of section 7(a)(2) of the Endangered Species Act. NPCA v. Jewell, 2014 U.S. Dist. LEXIS 152383, at * 13–* 14 (D.D.C. Feb. 20, 2014). The preamble to the proposed rule contains a complete discussion of the history of litigation surrounding the 2008 Stream Buffer Zone rule, see 80 FR 44449 – 444450 (July 27, 2015). OSMRE is underway with formal Section 7 consultation on the Preferred Alternative and will have received a Biological Opinion from the U.S. FWS prior to issuance of the Record of Decision and publication of the final rule. Should Alternative 9 or any other alternative instead become the Preferred Alternative OSMRE would consult with USFWS and revise the consultation documents as necessary. Therefore the 2014 ruling does not invalidate Alternative 9, the 2008 Stream Buffer Zone rule, as a possible alternative for consideration.

3. Cooperating Agency Involvement

Comment: Many commenters claimed that OSMRE could benefit further from the insight, experience, and best practices of the state regulatory authorities when developing the regulatory text, EIS, and RIA. These commenters often claimed that we did not provide the regulatory authorities that had agreed to be cooperating agencies in the NEPA process with the opportunity for meaningful engagement. As a consequence, these commenters noted that all but one of these regulatory authorities had terminated their cooperating agency status.

Response: OSMRE substantially engaged with stakeholders, including the regulatory authorities. A number of state agencies, including state SMCRA regulatory authorities, participated as cooperating agencies in the early development of the DEIS for the stream protection rule. These states provided meaningful input and comments that were used to prepare the DEIS. In addition, the DEIS was made available for all cooperating agencies and the public to review and provide input on during the public comment period. The public comment period was extended to provide interested parties, including the states, more time to review and comment on the DEIS. OSMRE conducted six public hearings in Colorado, Kentucky, Missouri, Pennsylvania, Virginia and West Virginia during the public comment period. Ultimately, OSMRE received approximately 95,000 comments, including hundreds of pages of comments from state SMCRA regulatory authorities, on the DEIS, Draft RIA, and the Proposed Stream Protection Rule.

In response to this and other feedback, OSMRE retooled the DEIS over the next several years and made it available for public comment on July 16, 2015. It was during the time that we were revising the DEIS that many of the state regulatory authorities grew frustrated with their role in the process, and all but one of the state regulatory authorities voluntarily terminated their role as cooperating agencies. Although not required to do so, on October 7, 2015, we invited these former cooperating state agencies to re-engage as cooperating agencies under NEPA. None accepted this invitation although some did submit comments on the proposed rule, DEIS, and Draft RIA. The Department’s Assistant Secretary for Land and Minerals Management, the Director of OSMRE, and other OSMRE officials remain available for engagement and discussion with the states and have continued to meet with representatives of states since the close of the comment period. In addition to meetings with the state SMCRA regulatory authorities in conjunction with Interstate Mining Compact Commission meetings, Department of the Interior and OSMRE representatives have either met with or held telephone or video conferences with 14 different state regulatory authorities since the proposed rule was published. In addition, OSMRE held six technical meetings in its regional offices on April 14, and 21, 2016, which were open to all state regulatory authorities.

We understand the state regulatory authorities wanted more input, not only in the development of the DEIS and FEIS, but also in the rule and the RIA. However, we have met our obligations as set forth in the Administrative Procedure Act, NEPA, and the pertinent Executive Orders and have sought and addressed the input from state regulatory authorities at crucial junctures in the development of the rule, RIA, and NEPA analysis. These are the points where their insights could best shape the proposal and refine the final rule without impinging on our deliberative process and our ability to craft a rule to meet our purpose and need. The FEIS has been shaped by this direct input as well as the information we have gleaned through our oversight of the state programs.

4. Compliance with Statutory requirements and Regulations

Comment: Several commenters stated that the Draft RIA and DEIS did not include an assessment of impacts as required under Executive Order 12866, as well as Unfunded Mandates, Energy Impacts, Analysis of Children's Health, and Federalism. Some commenters state that OSMRE fails to demonstrate how the proposed and final regulation will improve the performance of the economy without imposing unacceptable or unreasonable costs on society.

Response: The Final RIA and FEIS evaluate the benefits and costs of the Final Rule, along with other economic, distributional, and equity impacts. The Final RIA and FEIS satisfy the requirements for regulatory review under Executive Order 12866 (E.O. 12866) – *Regulatory Planning and Review*. E.O. 12866 (1993, as amended by Executive Order 13563 (2011)), which directs Federal agencies to consider the costs and benefits of available regulatory Alternatives and to select approaches that maximize net benefits, unless a statute requires another regulatory approach. The Office of Management and Budget's (OMB) Circular A-4 further elaborates on the characteristics of a "good" regulatory analysis. Specifically, Circular A-4 states that an economic analysis should provide information allowing decision makers to determine that:

- There is adequate information indicating the need for and consequences of the regulatory action;
- The potential benefits to society justify the potential costs, recognizing that not all benefits and costs can be described in monetary or even in quantitative terms, unless a statute requires another regulatory approach;
- The regulatory action will maximize net benefits to society (including potential economic, environmental, public health and safety, and other advantages; distributional impacts; and equity), unless a statute requires another regulatory approach;
- Where a statute requires a specific regulatory approach, the regulatory action will be the most cost-effective, including reliance on performance objectives to the extent feasible; and

- Agency decisions are based on best reasonably obtainable scientific, technical, economic, and other information.[1]

OSMRE has conducted a rigorous analysis that follows analytic standards set forth by OMB. As described in the RIA, the primary steps undertaken in developing the RIA include the following:

- **Defining the baseline conditions:** The first step involves estimating current and expected future conditions in the absence of the rule. The baseline includes the existing regulatory and socioeconomic burden imposed on regulated entities potentially affected by the Final Rule; the factors that will impact demand for coal absent this rulemaking; changes in industry practices absent the rulemaking; and changes in the location and structure of the industry absent the Final Rule.
- **Determining the regulated industry response to the Final Rule:** The next step in the analysis involves forecasting the behavioral response of the regulated community to the new rule. Specifically, for this analysis, we develop 13 “model mines” of varying size, geographic location, and mining method, and evaluate how the mining industry will adapt to the new requirements under each alternative.
- **Estimating the total regional and national changes in costs:** The third step is to model, at the regional level, the increase in the cost of coal production resulting from the requirements of the rule and changes in industry behavior. We also estimate costs borne by regulation and enforcement officials (i.e., government) as well as the costs incurred by the regulated community.
- **Estimating welfare losses and economic impacts:** Changes in the cost of producing coal will either result in lower profits to coal producers, and/or higher prices to coal consumers. Higher prices to consumers will result in reduced demand for coal, and will generate changes in economic welfare. Changes in the cost of producing coal in each region may also impact the regional distribution of coal production (i.e., favor some regions and coal production methods over others).
- **Estimating the potential benefits of the regulatory action:** This step involves assessing the benefits of the regulation and quantifying and monetizing those benefits to the greatest extent possible. Benefits are expected to result when changes in industry practices lead to greater environmental or human health protection. Benefits can also result if there is a shift in production to less-environmentally sensitive regions, or to a less environmentally damaging production technique.
- **Assessing distributional impacts:** In addition to estimates in costs and benefits on the net effects of the regulations, stakeholders and decision-makers are interested in the effects of the regulations on specific groups, such as small businesses, specific geographic areas, or governments.
- **Analysis of the alternatives:** OMB directs agencies to consider alternative regulatory schemes, such as different enforcement methods, degrees of stringency, requirements for different sized firms, requirements for different geographic regions, and market-oriented approaches. We compare the results for the nine alternatives considered and highlight how their impacts likely differ.

The results of the RIA are summarized in the RIA Executive Summary. As shown, compliance costs for the final SPR are expected to be $81 million annualized (2014 dollars). Average annual impacts on coal production are anticipated to be 0.7 million tons per year for the Preferred Alternative. Other quantified impacts in addition to a measure of impacts to overall social welfare, include coal prices, electricity

---

[1] Office of Management and Budget (OMB). 2003. Circular A-4: Guidance on Development of Regulatory Analysis. Issued September 17, 2003.

production costs, employment, severance taxes, environmental resources and human health. Impacts are also estimated for the eight other regulatory alternatives considered by OSMRE for use by decision makers.

The supporting SPR analyses also include the assessment of other equity considerations and regulatory impacts, including an assessment of Unfunded Mandates (UMRA), energy impacts (EO 13211), environmental justice (EO 12898), children's health protection (EO 13045), Tribal governments (EO 13175), and Federalism (EO 13132). In particular, the analyses address requirements related to the following:

- **Regulatory Flexibility Act (RFA) of 1980, as amended by the Small Business Regulatory Enforcement Fairness Act (SBREFA) of 1996**. The RFA (codified at 5 U.S.C. §§ 601-612), as amended by SBREFA (Pub. L. 104-121), requires Federal agencies to prepare a regulatory flexibility analysis and take other steps to assist small entities -- unless the agency certifies that a rule will not have a "significant economic impact on a substantial number of small entities." The Small Business Administration's (SBA) *A Guide for Government Agencies: How to comply with the Regulatory Flexibility Act* walks Federal agencies through the process of preparing screening analyses and initial and final regulatory flexibility analyses. The Regulatory Flexibility Act analysis for the SPR is provided in Appendix A to the RIA.
- **Unfunded Mandates Reform Act (UMRA) of 1995.** UMRA (codified at 2 U.S.C. § 1501 *et seq.*) requires Federal agencies to assess the effects of their regulatory actions on State, local, and Tribal governments and the private sector. Under section 202 of UMRA, Federal agencies must prepare a written statement, including a cost-benefit analysis, for rules that may result in the expenditure by State, local, and Tribal governments, in the aggregate, or by the private sector, of $100 million or more in any one year. The UMRA analysis incorporates the analysis conducted in the main text of the RIA and is provided in Chapter 9 of the RIA.
- **E.O. 13211 – *Actions Concerning Regulations That Significantly Affect Energy Supply, Distribution, or Use*.** E.O. 13211 directs Federal agencies to "weigh and consider the effects of the Federal Government's regulations on the supply, distribution, and use of energy." Agencies must prepare a Statement of Energy Effects for regulations meeting the definition of a "significant energy action." The energy impacts analysis is provided in Chapter 9 of the RIA.
- **E.O. 12898 – *Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations.*** E.O. 12898 directs Federal agencies to prioritize achieving environmental justice by identifying and addressing disproportionately high and adverse human health or environmental effects of their programs, policies, and activities on minority and low-income populations. This analysis is provided in Chapter 4 of the EIS.
- **E.O. 13045 – *Protection of Children from Environmental Health Risks and Safety Risks.*** E.O. 13045 directs Federal agencies and departments to evaluate the health effects of health-related or risk-related regulations on children. For economically significant rules concerning an environmental health or safety risk that may disproportionately affect children, E.O. 13045 also requires an explanation as to why the planned regulation is preferable to other potentially effective and feasible Alternatives. The findings for this analysis are presented in Chapter 9 of the RIA. While the environmental protection provisions of the Final Rule may improve health conditions for children, the Final Rule is not subject to E.O. 13045 because it does not involve decisions on environmental health or safety risks that may disproportionately affect children**.**

- **E.O. 13175 – *Consultation and Coordination with Indian Tribal Governments.* E.O. 13175 and Secretarial Order 3317 – *Department of the Interior Policy on Consultation with Indian Tribes***, address related unfunded mandate concerns with respect to the sovereignty of tribal governments, and impose requirements on Federal agencies to develop accountable processes to ensure "meaningful and timely input by tribal officials in the development of regulatory policies that have tribal implications." OSMRE provides this analysis in Chapter 5 of the EIS of the Final Rule.
- **E.O. 13132 – *Federalism.*** E.O. 13132 requires agencies to develop a process to ensure "meaningful and timely input by State and local officials in the development of regulatory policies that have federalism implications." Policies that have federalism implications are defined in the Executive Order to include regulations that have "substantial direct effects on the States [in terms of compliance costs], on the relationship between the national government and the States, or on the distribution of power and responsibilities among the various levels of government." In addition, policies have federalism implications if they preempt State law. The findings of this analysis are presented in Chapter 9 of the RIA. As discussed, government agencies are expected to bear annualized costs on the order of $0.5 million.

5. Regulatory and Energy Market Baseline for Analysis

Comment: Several commenters stated that the Draft RIA and the DEIS consider an incorrect regulatory, environmental, and/or market baseline. For example, commenters state that OSMRE's forecasts of the regulatory impact of the Proposed SPR are not based on realistic business or national economic forecasts or socioeconomic considerations. Commenters also state that a large amount of time has passed since OSMRE first raised the issue of the need for additional stream protection under SMCRA, and that a significant amount of other new federal water quality and stream protection measures, policies and guidance have been developed and implemented, or are in the process of being implemented. Commenters state that the baseline/No Action Alternative should have considered proper enforcement of the existing regulations as the regulatory baseline. They allege that proper enforcement and pre-existing mechanisms, such as NPDES permits under the Clean Water Act Section 303, would achieve a level of environmental protection to streams similar to the proposed SPR without the additional requirements. Additional comments addressed issues of scale, stating that our approach should be more oriented towards local and county-level impacts and initial conditions.

Response: As described in section 3.3 of the RIA, best practices in the conduct of regulatory impact analysis dictate that the meaningful measure of the incremental impact of a rule requires comparing the state of the world absent the rule (i.e., the regulatory baseline) with the state of the world with the rule.[2] The baseline should reflect compliance actions that are already being undertaken by the industry due to other regulatory requirements as well as ongoing market trends and conditions. The baseline demand for coal from a given region will be influenced by numerous exogenous factors (i.e., factors unrelated to this rulemaking), including: reserve depletion; changes in relative production costs; changes or limitations in transportation capability and cost; growing demands for low-sulfur coal; the abundance of, and relative cost of, alternatives to coal for electricity production (especially natural gas); changes in demand for steam coal resulting from the adoption of renewable portfolio standards for utilities; changes in demand

[2] OMB, Circular A-4, 2003.

for metallurgical coal (driven by domestic levels of iron and steel production, as well as demand from overseas); and changes in demand in the U.S. export market. Our model assumptions about future coal demand and supply are discussed in Chapter 5 of the RIA and Appendix F.

The OSMRE RIA and FEIS evaluate the impacts of the rule against a baseline that includes existing regulations affecting coal production and markets and reflects a reasonable projection of coal market trends over time. Given the current regulatory and market uncertainty, the RIA analysis measures the potential impacts of the Proposed Action against three alternative baseline coal market forecasts, including one where coal demand is lower and one where coal demand is higher than the primary base case. The baseline forecasts have been updated in the Final RIA to reflect the changing conditions in the coal industry. The RIA provides a comparison of OSMRE's forecasts to the U.S. Energy Information Administration (EIA) forecasts.

Due to the broad geographic scope and timeframe for the analysis, we are unable to forecast conditions at every future mine site as part of this national-scale EIS. The 13 model mines across the seven major coal regions were developed in order to capture regional variability in terms of mining methods as well as regional context as much as was feasible.

With regard to uncertainty within the analysis, there is substantial uncertainty regarding future impacts of the Rule. This results from a number of factors including uncertainty within the energy market, regulatory environment, and specific industry behavior. We address these uncertainties by conducting sensitivity analyses, providing ranges of potential impacts, applying multiple discount rates, and acknowledging the uncertainties throughout the analysis and in tables at the end of each chapter of the RIA.

6. Technical Accuracy

Comment: Several commenters stated that the RIA and EIS contain numerous technical inaccuracies, factual errors, and misrepresentations of current surface and underground mining practices throughout the U.S. Commenters alleged that the RIA relies upon environmental, mining industry, and economic data and assumptions that are vague and difficult to substantiate with publically available technical facts, current industry practices, and social conditions. They assert that OSMRE's interpretations of socioeconomic conditions, electric power markets, mining practices, and environmental conditions are not grounded in reality. Moreover, commenters contend that the RIA largely ignores relevant and plausible direct and indirect responses to the implementation of the Proposed Rule, such as reduced mining activity, job losses, changes to disposable incomes in local communities, and increased dependence on government health care due to unemployment. One commenter stated that the DEIS does not accurately or reasonably portray the environmental, social, or financial impacts of the SPR on the mining industry, local and state economies, or the nation.

Response: In evaluating regulatory impacts, OSMRE is charged with estimating the incremental costs and benefits of the Proposed Rule according to Federal agency guidance and best practices as called for under E.O. 12866 and described in OMB's Circular A-4. According to these best practices, RIA evaluates changes in "social welfare" brought about by a regulation, typically measured in terms of changes in producer and consumer surplus. This reflects changes in the value of goods and services gained and/or lost by society due to compliance with the rule. Consistent with this guidance, the OSMRE RIA accordingly quantifies the compliance costs of implementing the rule using the best available data and models, as well as the broader social welfare effects of the rule applying well-accepted economic methods. In addition to OSMRE input, primary data sources for the analysis include the following: Mine Safety and Health Administration (MSHA), United States Census Bureau; Bureau of Labor Statistics (BLS); U.S. Energy Information Administration (EIA); U.S. Environmental Protection Agency (U.S. EPA); U.S. Army Corps of Engineers (USACE), an engineering design and analysis for 13 mines conducted by industry mining engineers; Moody's Analytics, National Oceanic and Atmospheric Administration data, reported power plant capacity additions and retirements, State renewable portfolio standards, propriety coal transportation databases, publicly traded coal company filings (reserves, costs, mine activity), publicly traded gas and transportation company Form 1 filings, utility integrated resource plans. The analysis includes an assessment of implications of the rule on coal production (mining activity), employment, changes in income, as well as potential implications for public health and safety, and quality of life, among other considerations. The RIA and EIS attempt to recognize key uncertainties throughout the analyses, and includes several sensitivity analyses conducted for key assumptions. In particular, the energy market modeling efforts incorporate a range of three potential baseline forecasts for coal production in order to take into consideration the high level of coal market forecasting uncertainties that exists. The engineering analysis conducted a number of sensitivity analyses to particular assumptions.

7. Water Quality Benefits

Comment: Commenters question whether the scientific data provided in the Draft RIA and DEIS is sufficient to show that mining causes adverse impacts to water quality. Commenters also state that the SPR is not necessary because existing regulations, such as the National Pollutant Discharge Elimination System (NPDES), are sufficient to address potential issues. Commenters state that OSMRE's method for determining affected streams is fraught with errors and uncertainties. Commenters question, in particular, the use of a study finding that the downstream effects from mining extend approximately 6.2 miles from the mine site in West Virginia to calculate downstream effects for all coal regions across the U.S. without any apparent adjustments for the distinct differences in topography, geology or hydrology between the coal producing regions. Additionally, commenters state that the incremental stream benefits anticipated to result from the SPR represent improvements to a relatively small share of overall water in resources in affected regions. As such, commenters conclude that the requirements of the SPR, in comparison to the projected benefits, appear to be extreme.

Response: Section 4.2.1.1 of the DEIS summarizes the available scientific literature characterizing the negative effects of mining under the baseline regulatory environment (No Action Alternative) on downstream water chemistry, including in areas outside of Appalachia. These studies find, in particular, elevated levels of arsenic, selenium, iron, aluminum, sulfate, and manganese, as well as increased acidity and elevated conductivity in downstream waters from coal mining sites, and demonstrate the need for additional regulation focused on reducing these impairments.

The DEIS then summarizes the literature relating coal mine management and reclamation practices to water quality impacts, both positive and negative. For example, the DEIS describes the science relating both excess spoil fills and coal mining through streams to increased sulfate, bicarbonate, calcium, and magnesium concentrations, as well as elevated conductivity levels, in downstream waters. Additional studies characterize the benefits of establishing riparian buffers at mine sites to reduce the sediment and chemical runoff that reach streams. Other studies show that consistent and regular monitoring practices are key to identifying and addressing specific water quality issue at given sites. Based on this information, OSMRE targets these specific management practices in order to reduce the effects of mining on downstream water quality.

OSMRE agrees that data are currently insufficient to develop a model that forecasts a specific level of water quality improvement expected from the SPR (e.g., a specific reduction in the presence of a particular contaminant or improvement in stream health metrics, such as EPT richness) downstream of each future mine site.

In light of current data limitations and in order to provide perspective on the level of downstream water quality benefit generated by the rule alternatives, the EIS estimates the downstream stream distance over which adverse effects of mining may occur absent the rule using a number of factors, most of which rely on region-specific data. These adversely affected streams are expected to benefit from improved management practices as part of the SPR. The region-specific multipliers estimating the downstream distance of impairments applied in the analysis integrate information on: the average size of mine sites in each region; the number of intermittent and perennial streams that have crossed mine sites on average in each region (ephemeral streams were not included in the analysis of downstream water quality benefits); and the distance over which the negative water quality effects persist. The estimated disturbed area associated with coal mines in each region derives from coal mine permit data from each coal mining region. The number of intermittent and perennial streams crossing mine sites is based on data identifying existing and past coal mine locations and USGS data on locations of streams across the U.S and is specific to each region. The estimated linear distance of stream over which negative effects of coal mining persist downstream of a mine site (approximately 6.2 miles downstream) is based on a study of mine sites in Appalachia. Comparable literature was not identified that provides information on how the downstream distance may vary in other regions. This downstream extent factor is combined with data on the number of streams present on the site in each region to arrive at an estimate of the number of downstream stream miles that may be adversely affected by mining activities. The EIS acknowledges the uncertainties associated with this estimate in the methodology; however, the analysis provides a valid basis for making relative comparisons between the alternatives under consideration.

By factoring in region-specific information on average mine size, number of streams affected, and coal production, the analysis uses the region-specific multipliers that examine the length of stream that is affected by mining per million tons of coal produced. As shown in Section 4.2.1 of the EIS, these multipliers are larger in Appalachia than in other regions. That is, more streams are affected per ton of coal produced in Appalachia than elsewhere in the U.S. Specifically, the analysis finds that on the order of 0.6 and 0.8 stream miles are impaired per million tons of coal produced in Appalachia, compared to 0.01 stream miles impaired per million tons of coal produced in the Northern Rocky Mountains and Great Plains Region. The difference is due to the greater production levels and larger aerial extent of mines in the Northern Rocky Mountains and Great Plains Region, and to the greater density of intermittent and perennial streams in Appalachia. Ultimately, the analysis finds that the majority of the estimated water quality improvements occur in Appalachia, while downstream water quality impacts in other regions are limited. We have added some additional text in EIS section 4.2.1.1 to clarify how this analysis was conducted. Chapter 2 of the EIS provides a discussion of the selection of Alternative 8 as the Preferred Alternative.

8. Monetizing Environmental Benefits

Comment: Multiple comments expressed concerns regarding the analysis of benefits of the rule. In particular, commenters argued that benefits should be monetized. The comments suggested that the analysis should monetize benefits by estimating a reasonable range of economic values associated with the impacts, for example by "making overall assumptions about water use (e.g., 40 percent of streams are used for recreation, 60 percent are near population centers, etc.)." In the absence of monetized benefits, two comments state that the RIA fails to employ recommended alternative methods of exploring whether the benefits of the Proposed Rule are justified by the costs, including cost-effectiveness analysis, break even analysis, and Net Environmental Benefits Analysis (NEBA). Absent monetized benefits, these comments assert that it is not possible to conclude that benefits from the Proposed Rule exceed costs.

Response: OSMRE agrees that a comprehensive monetized accounting of costs and benefits is the most straightforward way to evaluate the effectiveness of regulations where this is possible. OSMRE further agrees that methods exist to monetize many of the types of economic benefits associated with this Rule. The economics literature demonstrates a long history of monetizing, for example, improvements to water quality or availability of forest habitat for recreational activities. The findings of some of the most relevant literature are summarized in Chapter 7 of the RIA and Chapter 4 of the EIS. Studies valuing environmental improvements are, however, highly context-specific and a reliable benefit transfer of their findings is generally not appropriate at the much broader regional level on which the RIA is focused. In addition, generalized assumptions about potential future mine site characteristics would be speculative and, while leading to a monetized benefit, would not provide better decision-making information to OSMRE.

The RIA complies with guidance for regulatory impact analysis from OMB in Circular A-4, which recognizes the difficulty in monetizing particular types of benefits and does not suggest forcing monetization where data and methods are too limited to provide defensible estimates. Specifically, OMB states:

> "You should monetize quantitative estimates whenever possible. Use sound and defensible values or procedures to monetize benefits and costs, and ensure that key analytical assumptions are defensible. If monetization is impossible, explain why and present all available quantitative information. For example, if you can quantify but cannot monetize increases in water quality and fish populations resulting from water quality regulation, you can describe benefits in terms of stream miles of improved water quality for boaters and increases in game fish populations for anglers. You should describe the timing and likelihood of such effects and avoid double-counting of benefits when estimates of monetized and physical effects are mixed in the same analysis.... If you are not able to quantify the effects, you should present any relevant quantitative information along with a description of the unquantified effects, such as ecological gains, improvements in quality of life, and aesthetic beauty. You should provide a discussion of the strengths and limitations of the qualitative information. This should include information on the key reason(s) why they cannot be quantified." (Circular A-4, 2003).

Consistent with this guidance, the benefits analysis in the RIA applies the best available information to evaluate how implementation of the Final Rule (and the regulatory alternatives) will improve environmental performance of coal mining activities, thereby reducing environmental degradation and enhancing ecosystem services. Exhibit 7-1 of the RIA summarizes all categories of benefits expected to result from the Final Rule both in biophysical terms and how these improvements relate to ecosystem service benefits. Exhibit 7-2 then describes which metrics could be reliably quantified and monetized given available information.

Given available data, the analysis is unable to reliably quantify all of the economic benefits of the Final Rule. For four categories, the analysis quantifies the benefits in terms of biophysical changes (i.e., units of the resource, such as stream miles or acres of forest). In addition, the Final RIA includes one type of benefit -- reduced greenhouse gas emissions – as a monetized benefit. The analysis emphasizes that the quantified metrics alone do not present a complete picture of the benefits of the rule, and provides qualitative information on how these environmental improvements improve people's well-being.

The alternative frameworks suggested by the commenters do not provide OSMRE with more or better information than the current RIA framework. Specifically, as OMB describes in Circular A-4, cost-effectiveness analysis (CEA) can be misleading where the effectiveness measure does not appropriately weight the consequences of the regulatory alternatives. "For example, when effectiveness is measured in tons of reduced pollutant emissions, cost-effectiveness estimates will be misleading unless the reduced emissions of diverse pollutants result in the same health and environmental benefits (Circular A-4)." As noted above (and also noted in the public comments on the Draft RIA), the extent to which water quality or forest quality improvements result in social welfare benefits (e.g., reduced health risk or improved recreational activities) varies significantly by site (e.g., different exposure pathways or variable accessibility for recreation). Thus, the quantified environmental benefits in the RIA are not appropriate for use in a CEA framework at a generalized regional level. Instead, the quantitative information on the environmental benefits is presented alongside qualitative information describing the link to improved social welfare, and the site-specific factors influencing this benefit.

Break-even analysis provides information on how small the value of the non-monetized benefits would need to be before the rule would yield no net benefit. This information is recommended in particular where some of the benefits are monetized and information is required on the level of significance of the non-monetized benefits and whether adding them to the monetized benefits would be expected to result in a net beneficial rule (or change the relative net benefits across regulatory alternatives). Given that none of the direct benefits of the rule are monetized, the estimated costs implicitly represent a break-even "threshold" for a net beneficial rule. While the direct benefits are not monetized, the qualitative information in the analysis is focused on providing information on the potential magnitude of the various benefit categories.

Finally, in general, the "NEBA Approach" referenced in this comment utilizes the same general principle applied in the RIA to consider benefits. That is, this approach involves measuring net environmental improvements (monetized or by other environmental metrics) so that alternative options may be compared by looking across all benefits metrics. However, the specific "NEBA Approach" referenced in this comment does not have precedent in a regulatory impact analysis context. This approach is most frequently applied to evaluate alternatives for oil spill planning and response, in particular to prioritize restoration and remediation activities for contaminated sites.

9. Public Health Effects

Comment: Several commenters stated that existing literature on human health impacts of mining does not support OSMRE's conclusions regarding human health benefits in the Draft RIA and DEIS. In addition, commenters state that OSMRE does not provide information within the water quality or public health sections of the Draft RIA and DEIS to demonstrate that the Proposed Action is expected to result in the reduced exposure of contaminants in drinking water sources. Lastly, a commenter suggested that the loss of jobs and a decrease in affordable health care would be caused by the Proposed Rule could worsen the health of sensitive subpopulations, including children, which the commenter believes falls under E.O. 13045.

Response: OSMRE provides available information within the water quality and public health sections of the Final RIA and EIS to demonstrate that the Final Rule is expected to result in the reduced exposure of contaminants in drinking water sources, by way of reduced contamination from coal mining activities. OSMRE acknowledges that more scientific research is needed to fully understand the causal relationships between mining related contaminant exposure and human health risks. However, while limited, the existing literature does associate mountaintop coal mining (a subset of surface mining activities) with an increased occurrence of human health related issues. Although these studies do not control for occupational exposure, the authors assert that because they have found positive associations in both men and women between proximity to mining operations and adverse health impacts, the effects are not strictly due to direct occupational exposure of coal miners, who are predominantly male. As stated in Section 4.3.4.1 of the FEIS, studies conducted to date attempt to control for other risk factors but more rigorous epidemiological studies are required to investigate these associations (e.g., long term prospective cohort follow up studies). In general, epidemiological studies are limited in their ability to prove a causal relationship, but continued positive findings obtained through a variety of study designs can provide a substantial weight of evidence in support of a causal relationship. The current body of evidence, while it does not reach that level, does suggest that further research on impacts of coal mining operations on nearby residents is warranted.

OSMRE appreciates the commenter's concern related to the impact that job loss and reduced availability of health care could have on children. However, E.O. 13045 (62 CFR 1985, April 23, 1997) applies to economically significant rules that concern environmental health or safety risks that U.S. EPA has reason to believe disproportionately affect children. Executive Order 13045 refers specifically to risks to health or to safety that are attributable to products or substances that the child is likely to come in contact with or ingest such as air, food, drinking water, water used for recreation, soil, and products exposed to children. These are elements in which the rule seeks to improve. The decrease in employment in the industry is anticipated to be small for the SPR relative to the total employment within the industry. Reduced access to health care is not an anticipated result of the SPR. OSMRE refers the commenter to the Environmental Justice Analysis as required by Executive Order 12898 presented in 4 Chapter of the EIS as it relates to disproportionately affected populations.

10. Model Mines Analysis

Comment: Several commenters are concerned that OSMRE did not evaluate any actual, operating mines for purposes of the RIA. Comments state that OSMRE relied on "model," "hypothetical" mines that theoretically represent various actual mining scenarios. Some commenters stated that OSMRE designed its models so that they would not experience any impacts, and then used the results of its model mine analyses to conclude that the SPR will not impose significant new compliance costs.

Response: The Executive Summary to the RIA notes that coal mining operations vary from region to region, within a region, and within a mining type in a given region. The specific characteristics of the large number and wide variety of coal mines in the United States make a mine by mine analysis impracticable. In addition, the population of active mines is expected to change over time; as such, the precise location and operating characteristics of the population of future mines, which are the primary target of the SPR, cannot be forecast based on publicly available data. Given a lack of a mine-specific forecast of future operations, it is not possible to forecast for specific existing or future mines how operations will change under the Final Rule. Instead, this analysis relies on a "model mine" analysis developed by Morgan Worldwide, Inc., which provides results that are extrapolated to the universe of mines affected by the Final Rule. A "model facilities" approach has been successfully employed in other contexts. The purpose of assessing the impacts of the Final Rule and the alternatives at the model mine level is to approximate how mining operations in each region might change operations or be designed in response to different requirements and elements of each alternative, and to develop metrics that can be used to further calculate the benefits and impacts of the alternatives.

The goal of the Model Mine analysis was to design mines that are representative of operations located in each region. However, the analysis recognizes that actual future individual mining operations are likely to vary in practice based on specific factors such as topography, geology, and hydrology that cannot be modeled in detail across a large scale. Therefore, the engineering analysis for the RIA and EIS describes impacts that would be expected to occur under similar conditions as those encountered by real operations but does not necessarily imply that the results would be applicable to all mining operations in a certain region.

The model mines were not predetermined in order to avoid showing impacts of the SPR. After establishing a mine in each coal region, MSHA coal production data were utilized to determine the individual mining methods that would represent each of the respective coal regions. Annual coal production levels were derived for each model mine from the MSHA data. In total, engineers designed and analyzed thirteen representative model mining operations, which are categorized by coal region and size of mine (tons of coal produced annually). The analysis also includes designs for five coal refuse facilities associated with underground mining operations.

The model mine analysis uses design elements from currently operating mines. Active mine permits with similar annual production tonnages to the regional representative tonnages were reviewed and used as a basis for designing the modelled mines. Specifically, actual permits were used to define coal seam thicknesses, life of mine coal reserves, depth of cover and stripping ratios, stream impacts, mine impact acreage, reclamation plans, and other pertinent information related to each operation. The geographic location of each active permitted operation was also used to identify a realistic mining location for each model mine. The proximity of the model mines to the associated actual permits ensured the terrain and geology of the model mine operation mirrored the permits, while not asserting particular findings for particular already-operating mines. Details of the model mines design process are included in Appendix B of the Final RIA.

11. Material Damage to the Hydrologic Balance (MDHB)

Comment: Several commenters stated that the RIA fails to accurately capture or depict underground mining operations and the real implications of the rule for these practices, failing to consider the possibility that longwall operations would cease entirely if the rule were to go into effect. Commenters were concerned that the evaluation of the concept of MDHB as applied in the RIA only includes analysis for a permanent diminution of stream loss, but the definition of MDHB in the Proposed Rule includes other criteria that could include MDHB attributable to longwall-induced subsidence as well as other mining operations. Commenters also questioned specific assumptions related to overburden depths at which permanent stream loss would not be expected.

Response: OSMRE clarified in the Final Rule and FEIS that the definition of material damage to the hydrologic balance outside the permit area does not apply to temporary subsidence impacts from underground mining. The rule text was revised to ensure that temporary subsidence impacts to streams and other water resources are corrected or repaired within a two-year period. This clarification was in response to concerns that the Final Rule could be interpreted so as to prohibit underground mining operations that could result in temporary impacts to streams.

The model mines were designed to reflect real conditions at mine sites in affected regions as much as possible. The assumed depth of the model mines were determined based on real geological conditions at permitted sites, and were not artificially lowered to avoid MDHB issues that could occur at shallow depths. Because MDHB issues are so site specific, it was not appropriate to evaluate these potential issues as part of the model mines analysis. As such, the potential impacts to longwall mining activities were evaluated on a regional basis to gain an understanding of the likelihood of potential issues arising given current methods. The EIS and RIA Appendix D merely note that the underground model mines as designed appear unlikely to result in MDHB issues, but does not draw broad conclusions based on this observation.

Regional overburden depths were used as a basis to evaluate the regions with regard to the likelihood of permanent stream flow loss as a result of underground mining. Although technical literature provided some guidance when determining threshold depths, no reference gave definitive answers with regard to a regional evaluation of permanent stream flow loss. The regional overburden depths included in Appendix D were derived from the technical material with an understanding of current mining practices and the number of instances of permanent stream flow loss that each region has experienced.

In cases where the analysis states that room and pillar mining could be used in lieu of longwall mining to protect streams from impacts, it recognizes that recovery will be less than longwall mining. Leaving coal pillars to protect streams is an expected and reasonable action where streams are likely to experience permanent stream flow loss. If a room and pillar mine is properly designed and the mine plan is correctly implemented, room and pillar mining should not cause permanent stream flow loss. While it may not be certain that room and pillar mining will not result in MDHB, it is much less likely to occur in room and pillar mining than in longwall mining because subsidence is likely to be less extensive in room and pillar mining. Therefore, this mining method was not evaluated in Appendix D of the Final RIA.

12. Stranded Reserves

Comment: Several commenters stated that the RIA and EIS ignore the fact that the SPR would result in vast volumes of stranded coal reserves that would no longer be economically feasible to extract.

Response:

As described in Chapter 5 of the RIA, stranded reserves would be reserves that are technically or economically mineable but are unavailable for production given the new requirements or restrictions of the SPR. The assumption by the commenters that "vast volumes" of coal would be stranded appears to be rooted in an assumption the Proposed Action would result in the total shutdown of the longwall industry. This is not anticipated (please refer for the Master Response to the National Mining Association comments for additional details). Instead, the primary impacts of the Proposed Action are anticipated to be increased costs to produce coal; this increase in costs is anticipated to reduce coal demand from utilities. This is different than stranding particular reserves.

As discussed in Chapter 5 of the RIA, a potential impact of the Final Rule is a reduction in physical access to some reserves (as opposed to increasing costs of coal production), which would reduce coal reserve values. We examine whether coal reserves may be "stranded" or "sterilized" – i.e., rendered effectively unavailable for production given the new requirements of the Final Rule, in addition to the cost effects of other rule requirements. We define stranded reserves as those that are technically and economically minable, but unavailable for production given the new requirements and restrictions included in the Final Rule. Stranding reserves would represent a market welfare cost that may not have already been captured in the assessment of the impacts of increased costs on coal production.

Our analysis indicates that there will be no increase in stranded reserves under any of the Alternatives. That is, the engineering analyses underlying the economic analysis determined that the same volume of coal could be mined under each of the Alternatives as under the baseline alternative. Even if there is no stranding of reserves, coal production may decline as shown in the results below. A decline in production does not necessarily imply that reserves are stranded. Instead, it may simply reflect reduced cost competitiveness for coal relative to other energy sources, which may slow the annual rate of production. In the hypothetical case, for reserves that mines would be unable to extract from the ground due to a Final Rule, the loss in reserve value would be the baseline value of these reserves, as represented by the present value of the *economic* profits that mines (or the land owner) would earn on these reserves over time, where economic profit is specified as the value of the coal, as extracted, minus the cost of extraction, including normal profits (i.e., opportunity costs of capital). Normal profit may be estimated based on the weighted average cost of capital to the coal mining industry. That is, the cost associated with stranding coal in the ground would be measured as the value of that coal in the ground to the mine operator or landowner.

Note that estimates of foregone reserve value would vary across different baseline scenarios analyzed, as baseline policies that encourage substitution to other fuels would reduce coal prices and slow the production rate for these reserves, both of which would reduce reserve value. An analysis of the change in reserve value for foregone reserves would rely on baseline market forecasts for coal (described below) for information on coal prices and production under each baseline scenario. Estimation of these reserve values would also reflect the cost of extracting these reserves (to assess profitability). Calculation of the welfare loss associated with the stranding of reserves would detailed information not only on the trends in coal prices over time, but also the likely timing of production for a given coal reserve, and the costs of production for a given reserve. Each of these variables introduces uncertainty into the assessment of reserve value.

13. Industry Operational Costs

Comment: Several commenters stated that the Draft RIA underestimates the significant increase in operational costs that will result from the Proposed Rule. Commenters stated that costs include direct compliance costs (including time delays) associated with the additional effort involved in permit renewal and applying for new permits that would not otherwise be required under the existing regulations; more frequent permitting that may be required to maintain productivity while working around stranded reserves; and the increase in costs and duration of baseline monitoring under the Proposed Rule, which would require data collection over twelve consecutive months (assuming that an extreme weather event is not encountered). Commenters alleged that although the methodology in the basic analysis is sound, OSMRE's calculation grossly underestimates the costs of the Proposed Rule.

Response: In evaluating regulatory impacts, OSMRE is charged with estimating the incremental costs and benefits of the Proposed Rule according to Federal agency guidance and best practices as laid out in OMB's Circular A-4. According to these best practices, a Regulatory Impact Analysis evaluates changes in "social welfare" brought about by a regulation, typically measured in terms of changes in producer and consumer surplus. This reflects changes in the value of goods and services gained and/or lost by society due to compliance with the rule. Consistent with this guidance, the Final RIA accordingly quantifies the compliance costs of implementing the rule using the best available data and models, as well as the broader social welfare effects of the rule applying well-accepted economic methods.

Compliance costs are comprised of industry administrative costs borne by private entities, costs associated with changes to operations and/or additional capital costs required to comply with the Proposed Rule (as borne by mine owners and operators), and costs to State and Federal governments (regulatory authorities) associated with implementing the rule. The Final RIA and FEIS evaluate how each rule element alone and in combination may affect future coal mining operations under each proposed alternative. The analyses include and quantify increased costs to the industry associated with baseline data collection and more frequent monitoring, as well as administrative time spent on permitting applications. In the Final RIA and FEIS, estimates of industry administrative and regulatory authority costs (including costs of monitoring as well as paperwork requirements associated with permitting) have been reconsidered and increased in response to public comments. The Final RIA and FEIS now also include quantified costs associated with delays related to bonding requirements in the SPR. Chapter 4 of the Final RIA describes the compliance cost estimation method in detail. Detailed assumptions about the administrative (paperwork and monitoring) requirements are presented as part of the PRA analysis in the preamble to the final rule. The EIS in Chapter 4.3.1 recognizes that the Alternatives will result in costs to the industry as well as RAs that include monitoring and permitting-related requirements. A sensitivity analysis was conducted on the major components driving compliance costs, including haulage costs, reforestation costs, production levels and stripping ratios. The results of this analysis are presented in Final RIA Appendix B, Attachment A.

14. Regulatory Authority Costs

Comment: OSMRE received comments stating that the Draft RIA and DEIS underestimate the costs of the proposed rule to state regulatory authorities. The commenters stated that funding for state regulatory and permitting staff in Ohio and match dollars for grants from the OSMRE are projected to decrease to a level that a number of employees will need to be transferred to other sections or positions will be eliminated. Some regulatory authorities stated that OSMRE considers the additional employment by regulatory authorities as an offset to the loss of employment in the coal industry and the associated unemployment that goes with reduced coal production. Other commenters stated that reductions in coal production have a direct impact to state permitting and regulatory staff numbers. Commenters stated that the Draft RIA and DEIS did not address the staffing needs and costs to regulatory authorities associated with increased monitoring, including requirements for experts in various scientific and technological areas that are currently not present or insufficient in many state regulatory authorities. Some commenters point out that the time and resources required to review a permit do not correlate to the amount of coal produced on a permit. Permit review times depend on the number, size, and most importantly, complexity of the permit. There is a large amount of variation in how state programs are run. Some have separate permit writers and inspectors; some do both permitting and compliance. These differences should be considered in the context of additional costs incurred by state regulatory programs.

Response: The estimates for regulatory authority costs have been revised in the Final RIA and FEIS to better reflect potential changes that are anticipated as a result of the SPR. As the commenters note, the proposed rule has the potential to increase costs to regulatory authority programs. As described in Chapter 4 of the Final RIA and Section 4.1 of the FEIS, these costs include costs associated with additional permitting requirements imposed by the alternatives. Additional analysis on costs expected to be experienced by regulatory authorities has been added to Section 4.1 of the FEIS. We note that the purpose of our analysis of these costs is to estimate the incremental costs to these programs due to the SPR over and above expenditures that would have already occurred under the baseline (or No Action Alternative). Thus, the aim of the analysis is not to estimate the total annual expenditures by these programs. After considering public comments, information on total baseline expenditures has been added to the analysis for context in Appendix H of the RIA. After considering public comments regarding the independence of budgets from coal demand, we have also revised the approach used to calculate these "government costs" (revised in the Final RIA and FEIS to be referred to as Regulatory Authority Expenditures) on a state-wide basis that is compared to program expenditures and is not assumed to be dependent on the amount of coal produced in a given year. As reported in Chapter 4 of the RIA, current regulatory authority program expenditures across the U.S. are estimated to be $88 million. The Final RIA and FEIS estimate that the SPR will result in an increase in costs to regulatory authority programs of approximately $0.6 million annually under the Proposed Action across all programs. These increased costs to the regulatory authorities are detailed in Section 4.5 of the RIA, Section 4.1 of the FEIS, and Appendix H to the Final RIA.

The overall decrease in forecast coal production due to the SPR is anticipated to be modest, totaling a reduction of approximately 0.08 percent for the Final Rule. While we recognize that this change may depress the need for regulatory authority staffing to some degree, permitting requirements are also anticipated to increase demand for regulatory authority resources, including staffing, under the SPR. The FEIS and Final RIA recognize that the regulatory workload activity is dependent on the level of permits being administered and the number of new permit applications processed annually. These activities are in decline regardless of this Rule. It would be incorrect to say regulatory budgets and staff must increase from current levels as a result of the alternatives. The analysis does not assume that industry employment reductions that are estimated to result from decreased coal production will be offset by increases in government employment.

15. Industry Administrative Costs

Comment: Several commenters stated that industry administrative costs of the SPR to industry are understated. The commenters stated that significant increases in baseline collection, data sampling requirements per permit and adjacent areas, expanded sampling parameters, including biological sampling, increases in laboratory analyses costs and quality assurance/quality control (QA/QC) of baseline sampling, and engineering monitoring requirements, will have a greater impact on the coal industry than the Draft RIA and DIES reported.

Response: OSMRE agrees that the SPR is likely to result in costs to operators, some of which include administrative time spent on permitting applications and other compliance-related activities. Specifically, the alternatives (with the exception of the No Action Alternative and Alternative 9) within the DEIS proposed monthly baseline data collection for surface and groundwater for a 12-month period, followed by quarterly monitoring until final bond release. The Final RIA and FEIS include industry administrative costs associated with baseline data collection and more frequent monitoring, as well as administrative time spent on permitting applications. Upon review and consideration of public comments, OSMRE has updated and revised these estimates in the Final RIA. These estimates have increased from the Draft RIA and DEIS to approximately $17 million for the Preferred Alternative (annualized at seven percent discount rate).

16. Alternative Analysis Provided by the National Mining Association (NMA)

Comment: Several commenters pointed to the alternative analysis provided by the National Mining Association, conducted by Ramboll Environ on the impacts of the SPR. Commenters compare the results of this analysis to those presented in the DEIS and Draft RIA and ask questions about the differences in the presented results.

Response: NMA submitted an analysis conducted by Ramboll Environ of the impacts of the SPR on the coal industry. In this analysis, Ramboll Environ conducted 36 interviews of "members"[3] regarding anticipated impacts of the SPR on recoverable reserves.[4] No information is provided about how this sample was selected or the response rate to interview requests. This raises questions that are not addressed in the analysis regarding how representative the sample is of all mines in the U.S. and regarding the potential for self-reporting bias.

Interviewees were asked to provide estimates of the volume of coal reserves that would not be accessible due to the SPR.[5] Ramboll Environ did not provide the results of this survey in their comments, which

---

[3] "Member sample of firms," presumably NMA members. See page ii. "The survey included data from 36 individual coal mines, from firms representing over 66 percent of the national coal production" (Ramboll Environ, 2015, p.12).

[4] "Based on the understanding of the rule and its potential impact on the industry, a list of informal questions was developed and used to conduct interviews with coal companies that would be impacted by the rule" (Ramboll Environ, 2015, p.12). "the response to the proposed rule was based on confidential discussions with firms regarding the context of the proposed SPR" (Ramboll Environ, 2015, p.34)

[5] "Companies provided the accessible reserves under the present situation (baseline), as well as the reduction in these reserves under one or more interpretations of the rule." (Ramboll Environ, 2015, p. 13)

complicates our ability to assess the reasonableness of the responses. While the interviewee responses are not provided, at the high-end the survey results would represent a significant shut down of the mining industry, with half of the surveyed mines closing (including 82 percent of the underground mines). The mines closed represented 90 percent of underground and 75 percent of surface mine production.

Ramboll Environ assumes that the interviewee estimates of "loss in reserves" at individual mines leads to a proportionate nationwide reduction in *annual coal production and job losses*.[6] Extrapolating the anticipated reduction in coal reserves in this way assumes no potential exists for adaptation or substitution to offset the loss in reserves at the surveyed sites (e.g., increased coal production at other sites or in other regions).

Ramboll Environ translates the decrease in production into a monetized "coal value at risk." This calculation involves simply multiplying the reduced production by the current regional average price of coal.[7] This method is a gross oversimplification of how a reduction in production would generate costs and is not consistent with well-accepted economic methods for evaluating costs of regulations.[8] For example, it does not consider that a large portion of the price of coal are costs that are not "lost" if the coal is not produced but rather are unspent.

The percent change in coal production (27 to 64 percent) is also applied to estimate the direct employment losses, or "jobs at risk" (40,038-77,520). The report then applies NMA multipliers from a 2014 study to arrive at an estimate of indirect jobs at risk.[9] Ramboll Environ also applies multipliers to the calculated "coal value at risk" of $13.9 to $28.7 billion to arrive at total impacts on output of $27 to $58 billion per year. All of the estimates are calculated assuming 2013 coal production levels and prices over time (not accounting for trends in the industry).

Best practices in the conduct of regulatory impact analysis dictate that the meaningful measure of the incremental impact of a rule requires comparing the state of the world absent the rule (i.e., the regulatory baseline) with the state of the world with the rule.[10] The baseline should reflect compliance actions that are already being undertaken by the industry due to other regulatory requirements as well as ongoing market trends and conditions. The Final RIA evaluates the impacts of the rule against a baseline that includes existing regulations affecting coal production and markets and reflects a reasonable projection of coal market trends over time. On the other hand, the Ramboll Environ analysis makes no attempt to forecast an analytic baseline over the timeframe for which the SPR would be implemented. Instead, the Ramboll Environ analysis conflates existing regulatory requirements (e.g., stream restoration required under the Clean Water Act) with the requirements of the Proposed Rule, and considers only the current

[6] "The decrease in reserves was applied to the actual production data in each region and type of mining in order to derive the anticipated loss in annual production due to the proposed rule." (Ramboll Environ, 2015, p. 13)

[7] "Reserve losses were used to estimate declines in production and projected job losses." (Ramboll Environ, 2015, p.13). Results are an expected decrease in 263.1 to 629.1 million tons of coal produced per year (roughly 27 to 64 percent of current coal production).

[8] Best practices in the conduct of regulatory impact analysis are described in: White House Office of Management and Budget, "Circular A-4," September 17, 2003.

[9] The NMA study estimated a national employment multiplier of 3.62 for the coal mining industry." (Ramboll Environ, 2015, pg. 26)

[10] OMB, Circular A-4, 2003.

price and production of coal as a single snapshot in time.[11] This is particularly odd in light of the fact that Ramboll Environ specifically presents a forecast contraction of the industry in Appendix A of its own analysis (Figure A-3, p.A-4). This contraction is not reflected in the calculations of the economic impacts of the SPR.

The Final RIA considers how mine operators may implement each of the SPR elements at different types and locations of mines across the country. Importantly, the Final RIA models changes in mine operations in accordance with OSMRE's intent in implementing the rule elements. Conversely, the Ramboll Environ analysis relies on an uncertain interpretation of the SPR requirements and, in fact, there seems to be a disconnect between the SPR elements as written, and their interpretation by Ramboll Environ and the surveyed members.

For example, the Ramboll Environ analysis of SPR impacts to underground mining appears to rely on an assumption that the proposed rule would not allow temporary impacts to the hydrologic balance for underground mining.[12] The only survey response data provided is presented as a "member example" in Appendix B. In this example, the underground mine plan assumes that no mining activities would be allowed under streams.[13] In quantifying this loss in activity as a result of the SPR, the Ramboll Analysis assumes that existing regulations, including the Clean Water Act, would have no effect on the ability to mine under the streams and therefore any restrictions would be solely due to the SPR. However, this is incorrect. In fact, NMA's own submitted comments on the rule recognize that SMCRA and other existing federal laws such as the Clean Water Act already protect stream disturbance.[14] Thus, the one example provided clearly understates the baseline, and therefore overestimates the impacts of the SPR.

Furthermore, at the high-end, the member example in Appendix B assumes that the SPR itself would result in a complete prohibition on all underground mining beneath intermittent, perennial, and ephemeral streams. In this way, the Ramboll Environ analysis reflects an extreme assumption that implementation of the SPR requires avoidance of all impacts to the hydrologic balance inside or outside of the permit area, permanent or temporary.[15] This is not the intent of the SPR and, again, it implies that no protections to the hydrologic balance outside the permit area are currently required by any regulations. There exists clear examples of recently permitted mines where modifications to mine plans have been made in order to avoid impacts to the hydrologic balance outside the permit area. Ramboll Environ understates the

---

[11] The OSMRE RIA calculates the incremental costs and benefits (above and beyond the baseline) of implementing the rule (on industry, as well as the broader social welfare impacts), which is its charge under Executive Order 12866, Federal agency guidance, and best practices as laid out in OMB's Circular A-4.

[12] While not clearly stated, the interviewers report that they encourage interviewees to "assume that the most challenging component of the regulation were to be eliminated." They state that these "most favorable" assumptions included the following: "With underground mines, respondents were encouraged to think about how they might mine if temporary damage to the hydrologic balance were to be considered acceptable." (Ramboll Environ, 2015, p.12).

[13] The maps "show how the mine plan is altered to avoid perennial and intermittent streams (first) and then altered again to show how the mining company would have to alter the mine plan to avoid perennial, intermittent, and ephemeral streams." (Ramboll Environ, 2015, Appendix B page 1).

[14] National Mining Association. Re: Proposed Stream Protection Rule, 80 Fed. Reg. 44,436 (July 27, 2015); Docket ID OSM-2010-0018. October 26, 2015.Page 179.

[15] While not clearly stated, the interviewers report that they encourage interviewees to "assume that the most challenging component of the regulation were to be eliminated." They state that these "most favorable" assumptions included the following: "With underground mines, respondents were encouraged to think about how they might mine if temporary damage to the hydrologic balance were to be considered acceptable" (Ramboll Environ, 2015, p.12).

baseline regulatory requirements for these mines and misinterprets the intent of the SPR. As a result, the Ramboll Environ analysis estimated economic impacts of the SPR are vastly overstated.

Even if Ramboll's interpretation of the likely incremental changes in regulation of coal mines due to the SPR were appropriate, the approach to quantifying the resulting economic impacts is not. In evaluating regulatory impacts, OSMRE is charged with estimating the incremental costs and benefits of the Proposed Rule according to Federal agency guidance and best practices as laid out in OMB's Circular A-4. According to these best practices, Regulatory Impact Analysis evaluates changes in "social welfare" brought about by a regulation, typically measured in terms of changes in producer and consumer surplus. This reflects changes in the value of goods and services gained and/or lost by society due to compliance with the rule. Consistent with this guidance, the OSMRE RIA accordingly quantifies the compliance costs of implementing the rule using the best available data and models, as well as the broader social welfare effects of the rule applying well-accepted economic methods.

The Ramboll Environ analysis does not attempt to estimate compliance costs but instead relies on a single, self-reported measure of change (i.e., stranded reserves) from a sample of firms. The Ramboll Environ analysis neglects to provide information on how the population of firms interviewed was selected, as well as information on the specific questions and responses. Accordingly, how these firms estimated the magnitude of stranded reserves is significantly uncertain (aside from flawed interpretation described in the one example they provide, as described above). While industry input is helpful, we would need to better understand how the firms estimated the reserves that become stranded due to implementation of the rule in order for this input to be useful for regulatory decision-making.

The monetized values presented in the Ramboll Environ report are described as "impacts" of the Proposed Rule but, in fact, reflect the total value of the coal that it estimates becomes inaccessible due to the rule. These estimates should not be interpreted as social welfare impacts of the rulemaking and are therefore cannot be compared to the costs presented in the OSMRE RIA. In the case that all assumptions and methods leading to its calculation were reasonable, the "coal value at risk" may be a useful indicator of the changes associated with the rule; however, it is not the measure of economic impact put forth by the Office of Management and Budget as most relevant for regulatory decision-making. Translating stranded coal reserves into an economic impact would require accounting for multiple ensuing shifts in resources, including reductions in operational costs of coal production and increased production of potential substitutes. Simply stated, the total "coal value at risk" is not a measure of a cost of the regulation.

The percent change in coal production is also applied to estimate the direct employment losses, or "jobs at risk" (40,038 to 77,520). The report then applies NMA multipliers from a 2014 study to arrive at an estimate of indirect jobs at risk, resulting in total employment impacts of between 112,757 and 280,809.[16] At the high end this constitutes a 75 percent loss in current employment in mining and linked sectors. These estimates are in clear contrast to the employment impacts described in the OSMRE RIA.

The key factor driving the difference is the discrepancy between the two studies in the expected effects of the rule on coal production levels. The OSMRE RIA finds that the rule will result in only a minor

[16] The NMA study estimated a national employment multiplier of 3.62 for the coal mining industry." (Ramboll Environ, 2015, pg. 26)

reduction in overall coal production of less than one percent (although the magnitude varies by region). The Ramboll Environ analysis, as noted above, estimates a potential reduction in production of up to 64 percent.

Overall, the Ramboll Environ analysis does not constitute a meaningful evaluation of the economic impacts of the SPR, as proposed. The interpretation of the incremental changes in mining operations required to comply with the rule elements is inaccurate and extreme, leading to erroneous estimates of the impacts on coal production and employment.

17. Employment Effects and Multipliers

Comment: Commenters state that OSMRE admits that the coal industry will lose employment as a result of the Proposed Rule. Commenters allege that the Agency, however, fails to recognize that a potential increase in compliance-related and "other energy" employment does not offset these job losses due to differences in required skills for these two types of employment. Commenters state that it is unlikely that displaced coal industry employees could easily uproot and move to a different region of the country, since the value of their housing assets are disproportionately low. Commenters also state that the overall job loss will actually be several orders of magnitude greater than predicted in the Draft RIA and DEIS. Commenters state that it is ludicrous to assume that there will be sufficient opportunities for the coal miners displaced by this rule to find employment in a position created by this rule or that any position created by this rule will have a salary commensurate with employment as a coal miner. Additionally, commenters state that the regional and local impacts of the SPR are not fully considered. Several commenters stated that existing literature supports the use of multipliers to quantify the indirect and induced economic effects of changes in the coal industry, especially with respect to employment, and that some form of a multiplier should have been used in the Draft RIA and DEIS analyses.

Response:

The FEIS and Final RIA assess the effect on employment in the mining industry from the change in the level of coal produced (or production-related employment impacts) and from the additional employment required for industry to implement the SPR (or industry implementation employment impacts). Coal production decreases are anticipated to have a negative effect on employment. At the same time, employment demand associated with industry implementation of the rule would have a positive effect on employment. Both effects are driven by implementation costs of SPR for the industry. These estimates vary year to year and across alternatives.

The analyses recognize that work requirements imposed on mining operations by the alternatives may include performing inspections, conducting biological assessments, and other tasks that require employment of highly trained professionals (e.g., engineers and biologists). Other increased work requirements associated with elements contained in the alternatives are expected to require similar skills as currently utilized by the industry (e.g., bulldozer operations). In general, while some of the increased employment demand may utilize existing mining labor skills (e.g., requirements that require additional earth moving), other employment demand from the Proposed Action may require other types of labor (e.g., biological monitoring, lab testing, paperwork). That is, some additional jobs created by the Action Rule may differ in skill requirements from the production-oriented jobs that would be reduced due to decreased coal production.

To the extent that production-related impacts lead to reductions in direct employment in the coal industry, additional indirect impacts on industries that supply goods and services to the mining industry as well as induced effects associated with loss of income associated with those industries, would be expected. However, these "ripple" impacts on the economy are likely to have both positive and negative effects, i.e., negative ripple effects would result from decreases in employment due to expected decreases in coal production, while increases in employment due to industry implementation-related effects could also result in ripple effects. As such, OSMRE recognizes the existence of these effects but does not quantify these in this analysis because the distribution and regional variation of these effects are even more difficult to anticipate with certainty than the direct employment effects. Inclusion of indirect and induced impacts would increase the potential total negative employment effects and also amplify the positive employment effects reported in the Final RIA and FEIS. It is also possible to have differences at the county or township level where coal expenditures would be net positive or negative, but such data for jobs multiplier does not exist. The final documents include additional clarification about the direct and nature of these effects in Chapter 6 of the Final RIA and Section 4.3.1 of the FEIS.

The analysis does not intend to describe sectors that would "offset" or "absorb" coal sector job losses. The Final RIA recognizes that employment in the coal industry may be reduced in some areas due to the SPR. The Final RIA notes that additional work requirements of the SPR may include performing inspections, conducting biological assessments, and other tasks that require employment of highly trained professionals (e.g., engineers and biologists). Other increased work requirements associated with elements contained in the Final Rule are expected to require similar skills as currently utilized by the industry (e.g., bulldozer operations, haulage activities). The Final RIA quantifies the level of employment expected to be reduced within the industry and does not speak to how or whether particular individuals would seek job retraining. We note that Section 507(c) of SMCRA, 30 U.S.C. § 1257(c), establishes the small operator assistance program (SOAP). To the extent that funds are appropriated for that program, this provision of SMCRA authorizes OSMRE to provide small operators with training and financial assistance in preparing certain elements of permit applications. An operator is eligible to receive training and assistance if his or her probable total annual production at all locations will not exceed 300,000 tons.

The Final RIA and FEIS recognize that predicting and tracking specific employment effects of this Proposed Action on employment is difficult to disentangle from other ongoing economic and technological trends. The reaction of labor market to increased regulation is complex. As such, anticipating the future response of the coal industry to the Proposed Rule is challenging. Costs of complying with the Proposed Action are anticipated to result in changes to regional coal industry employment that will be added to and combined with ongoing trends.

18. Tax effects

Comment: Commenters state that the Draft RIA and DEIS attempt to predict impacts through the use of 2012 statistics which does not accurately reflect the recent precipitous drop in coal production and the corresponding decline in collection of coal severance taxes. Commenters were also concerned about the absence of an analysis of state ad valorem tax, federal mineral royalties, abandoned mine lands fees, black lung fees, and potential coal lease bonuses and sales and use taxes.

Response: Severance tax values have been updated to 2014 in the Final RIA and FEIS, which reflects the reduction in coal production in recent years. OSMRE appreciates the commenter's concern relating to how the SPR will impact government revenue streams such as severance taxes, ad valorem taxes, AML fees, black lung fees, coal lease bonuses, and sales and use taxes. The Draft RIA and DEIS incorporated analyses of potential impacts of the rule alternatives, primarily focused on potential impacts to severance taxes. Chapter 6 of the Final RIA and Section 4.3.1 of the FEIS have been updated to include a more robust discussion of the potential impacts of the alternatives on other types of taxes that are levied on coal production or value.

OSMRE notes that the results of the analysis on the impacts of the rule alternatives on coal production are relatively small, representing less than 0.08 percent of annual coal production during the study period for the analysis. Because most of the taxes discussed above use coal production as the metric with which they are levied, this small change in production is anticipated produce similarly minor impacts on these tax collections. To illustrate the potential impacts of the alternatives on these other taxes, one can use the example of ad valorem taxes in Wyoming. Wyoming collected approximately $240 million in ad valorem taxes on coal production in Fiscal Year 2015. The average annual projected decrease in coal production in Wyoming as a result of the SPR is anticipated to be is 0.7 million tons of coal between 2020 to 2040 (in the primary base case). As such, the SPR would be expected to result in an annual reduction in ad valorem tax revenue across all recipient Wyoming counties of approximately $23,000 annually (2014 dollars, seven percent discount rate). This would represent a decrease, when compared with Wyoming ad valorem tax revenues collected in 2015, of approximately 0.01 percent. We recognize that some county and local governments rely heavily on the revenues from taxes on coal and other natural resource extraction, and, as such these relatively small impacts on revenues could have more significant effects on those communities.

Additional taxes are contingent on the value of coal property rather than on the value or level of production. These taxes include workers compensation taxes, corporate income taxes, sales and use taxes. These taxes would be reduced when corporate revenues and/or employment is reduced. Impacts on these taxes are not quantified in the analysis, but are anticipated to be small given the overall scale of the anticipated impacts of the SPR on coal production. The Final RIA and FEIS also acknowledge two coal-related excise taxes that are currently imposed by the Federal government: The Abandoned Mine Lands Reclamation Tax (also known as the reclamation fee or AML fee) and the Black Lung Excise Tax. Whether these taxes will continue to be imposed prior to and during the study period is uncertain (Collection of the reclamation fee is scheduled to end September 30, 2021 (30 U.S.C. § 1232(a)).) If either or both taxes are collected during the study period, revenue from them would be less than under the baseline because of anticipated reductions in coal production.

19. Effects on Small Businesses

Comment: Comments stated that OSMRE's analysis does not adequately take into account the differential effects of the Proposed Rule on small coal producers. Several commenters stated that the Initial Regulatory Flexibility Analysis (IRFA) should address potential impacts to public entities, including state, local, and Tribal governments. Commenters also stated that the SPR will have significant costs to small governments and threaten revenues. Commenters were also concerned that the IRFA excluded operating companies reporting less than 2,000 tons of annual production and inactive mines.

Response: The courts have held that the Regulatory Flexibility Act/Small Business Regulatory Enforcement Fairness Act (RFA/SBREFA) requires Federal agencies to perform a regulatory flexibility analysis to forecast impacts to small entities that are directly regulated. In the case of *Mid-Tex Electric Cooperative, Inc., v. Federal Energy Regulatory Commission (FERC)*, FERC proposed regulations affecting the manner in which generating utilities incorporated construction work in progress in their rates.[1] The generating utilities that expected to be regulated were large businesses; however, their customers -- transmitting utilities such as electric cooperatives -- included numerous small entities. In this case, the court agreed that FERC simply authorized large electric generators to pass these costs through to their transmitting and retail utility customers, and FERC could therefore certify that small entities were not directly impacted within the definition of the RFA.

Similarly, *American Trucking Associations, Inc. v. Environmental Protection Agency* (U.S. EPA) addressed a rulemaking in which U.S. EPA established a primary national ambient air quality standard for ozone and particulate matter.[2] The basis of U.S. EPA's RFA/SBREFA certification was that this standard did not directly regulate small entities; instead, small entities were indirectly regulated through the implementation of State plans that incorporated the standards. The court found that, while U.S. EPA imposed regulation on States, it did not have authority under this rule to impose regulations directly on small entities and therefore small entities were not directly impacted within the definition of the RFA.

Following the court decisions described above, the Final Regulatory Flexibility Analysis (FRFA) for the SPR considers only those entities that are directly regulated by the SPR. SMCRA and its implementing regulations regulate the activities of coal operators. Thus, it is these operators that are the focus of the FRFA. To the extent that small governments or Tribes are registered owners or operators of coal mines, impacts to these entities are reflected in our analysis, which is based on data on reported coal production from operating facilities.

The FRFA has been revised to include consideration of all mines that produced coal in the most recent MSHA data available for this analysis, regardless of whether MSHA labels the mine as “active” or not. The FRFA analysis does not include entities reporting less than 2,000 tons annual production in 2015 in its detailed tables. However, it now provides additional information to characterize these 48 mines. The total tonnage that all mines producing less than 2,000 tons each reported to MSHA in 2015 was 49,000 tons, or 0.005 percent of the total coal production in the U.S., most of which was in the Appalachian Region. Production from these 48 facilities averaged 1,000 tons in 2015. Over half of the facilities recording less than 2,000 tons (26 out of 48, or 54 percent), were labeled as temporary idle or abandoned by MSHA. Due to their very low output and status, this FRFA assumes that these facilities are not to be representative a typical small entity in the industry that would be affected by the SPR.

The FRFA describes not only the impacts of the rule on small entities as defined by SBA thresholds, but also provides additional detail describing potential impacts of the rule on operators with less than 20 employees. As shown, there were 188 operating mines, of which 167 are thought to be small entities, that reported production in 2015 and who recorded less than 20 employees. Impacts of the rule on these entities are anticipated to range from 0.1 to 3.1 percent of estimated annual revenues. The FRFA has been revised to discuss commenters’ concerns regarding the specific burdens faced by small operators.

[1] 773 F. 2d 327 (D.C. Cir. 1985).

[2] 175 F. 3d 1027, 1044 (D.C. Cir. 1999).

The FRFA acknowledges that some costs are more readily scaled to small operators than others; that is, some administrative burdens or other requirements could result in a more disproportionate cost to small operators. We note that Section 507(c) of SMCRA, 30 U.S.C. § 1257(c), establishes the small operator assistance program (SOAP). To the extent that funds are appropriated for that program, this provision of SMCRA authorizes OSMRE to provide small operators with training and financial assistance in preparing certain elements of permit applications. An operator is eligible to receive training and assistance if his or her probable total annual production at all locations will not exceed 300,000 tons.

20. Reforestation

Comment: Several commenters stated that there is too much emphasis and importance placed on the proposed reforestation requirements associated with SPR. Commenters stated that converting former mine lands to cropland or early succession, non-native grasses represents a better goal than restoring to native forest habitat in certain circumstances. Specifically, commenters argued that reclamation using native plant species and restoring habitat to native forest would diminish habitat quality for wildlife, which can impact recreation, and reduce ecosystem services, such as erosion control. Additionally, commenters stated that hunter harvest of deer and other wildlife game species have increased substantially in the past 30 years and that OSMRE fails to reconcile available state data and published studies with claims that reclamation has failed to attract and support wildlife. Furthermore, commenters stated that OSMRE offers no substantive information upon which to make judgments about wildlife populations and recreation (hunting) associated with each of the DEIS alternatives, and as such must clarify how it arrives at conclusions that the No Action Alternative is less desirable than other options.

Response: The existing regulations (the No Action Alternative) at 30 CFR 816.111 through 816.116 and 817.111 through 817.116 require use of native species in revegetation, although introduced species are permitted under certain conditions. The Action Alternatives (specifically, 2, 3, 4, 5, 7 and 8) would require additional measures as described in Chapter 4 of the FEIS (section 4.2.3.2). These advances under the Action Alternatives would enhance fish, wildlife, and related environmental values and ensure that the reclaimed site can support the uses it was capable of supporting before any mining, including the vegetation that it would support in the absence of human influence. The Action Alternatives would beneficially impact soil quality and productive capability both directly in the form of improved soil reconstruction requirements and indirectly in the form of improved revegetation requirements.

OSMRE acknowledges that there may be some adverse impacts associated with implementation of the Action Alternatives. The FEIS states that the impacts of the SPR on recreational activities may include both positive as well as negative impacts, stemming largely from rule elements that may lead to additional efforts to improve the conditions of post-mining landscapes, and increased reforestation efforts. However, the analysis also finds that the majority of post-mining land uses will remain unchanged from what would have already been expected without the rule. As such, improvements, as well as minor adverse impacts in the shorter term associated with some hunting activities, are anticipated.

OMSRE agrees that nature-based tourism, wildlife viewing, and hunting can contribute substantially to local and regional economies. Some of these activities occur on private lands. Elements of the SPR seek to reduce the short and long term adverse impacts of coal mining on the natural landscape. Thus, recreational opportunities on or near reclaimed mine lands could be enhanced following the SPR implementation, including on private lands. Unfortunately, the data on recreational visitation to private lands are inconsistent on a national scale, and do not provide sufficient data to understand the extent and quality of private land habitats and how these characteristics could be affected by the alternatives considered. The metrics captured in hunter harvest data (e.g. hunter success rates, days of effort per harvested animal, total days of effort, number of licenses sold) present a valuable snapshot of historic and current hunter activity. However this data provides no additional insight on expectations for future management of private lands or expectations of future hunter harvests with or without implementation of any particular alternative. Management of public lands is more predictable and subject to overarching goals that are established under public review. Nonetheless, following the public comment period, OSMRE has revised the recreation analysis to incorporate a data set that is inclusive of protected private lands in addition to public lands. In addition, OSMRE has reframed the analysis to focus on presenting the total state and regional levels of fishing, hunting, and wildlife viewing activity rather than attempting to allocate it to the study area.

Some commenters assume that more stringent proposed revegetation requirements will negatively affect recreational activities, particularly hunting. OSMRE acknowledges that replacing these forests and other native habitats with fast growing grasses entrains soil and other excavated material, which lowers short-term erosion potential, and may also enhance short-term hunting opportunities in early successional habitat. However, a consequence of this conversion is a reduction in long-term carbon storage potential, soil health, sediment entrainment, and suitable habitat for native fauna. The proposed revegetation requirements would re-establish native vegetation, which supports local species for recreational viewing and hunting. OSMRE acknowledges that reforestation can take a decade or more to occur, but mountain forest landscapes are popular for many recreational activities including hiking, hunting, wildlife viewing, and others.

21. Alaska

Comment: Several commenters stated that the characterization of Alaska and its resources is inadequate in the Draft RIA and DEIS. Citing Alaska's unique location, climate, and coal reserves, commenters feel that it is inappropriate to group Alaska with the contiguous states of Washington and Oregon in the Northwest Region. Commenters also noted that the analyses presented in the Draft RIA and DEIS center on too narrow of a region in Alaska by including the only active coal mine operation in Alaska as the greater Northwest Region designated by OSMRE. In doing so, the analysis excludes other potentially minable coal fields, such as those in the Arctic region of northwestern Alaska, and coal fields for which permits are currently being sought.

Response: Oregon and Washington are included with Alaska in OSMRE's Northwest Region. However, Oregon has not had coal mining in the past decade and coal production in Washington has been historically very low with no active mining at present. While these states are included in the Northwest Region, the discussion and analysis centers exclusively on the active coal mining operations in the State of Alaska.

The Northwest Region currently produces less than 0.5% of total coal production in the U.S. Despite relatively low coal production in Alaska, OSMRE designed a model mine for the region that reflects the state's unique location, climate, topography, geology, and hydrology. The model mine for Alaska was tailored to represent the currently operating mine in the Nenana coal field, such that the representative model mine produces two million tons of coal per year.

OSMRE recognizes the potential for new coal mine projects, but finds that assuming development of these areas in current forecasts of State production would be speculative at this time. In particular, OSMRE acknowledges in the Final RIA and FEIS that there are permits being sought to mine in other areas within Alaska, including the Beluga Coal Fields. However, the future status of those developments is not known. OSMRE is not forecasting an increase in production to occur in the near future in these areas given anticipated coal market conditions. We note that, late in 2015, Usibelli opted to suspend coal exports for the remainder of the year citing low demand in Asia, which further supports an assumption that coal production in Alaska is not increasing in the foreseeable future.

K.3 Detailed Comment Table

As stated above, each written comment was carefully reviewed; substantive points were identified and responded to by OSMRE. The following table provides these detailed comments with OSMRE's response, identifying any action taken within the analysis to address a commenter's concern.

1. General

GENERAL			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
OSM-2010-0021-0030	Anonymous	Section 702 Says that SMCRA should only fill in gaps that the CWA oes not cover. Between Sections 303, 401, 402, and 404 I cannot see any gaps. If there are some talk to the CWA agencies.	Please see the discussion of the need for a nationwide rule contained within the rule preamble.
OSM-2010-0021-0046	Anonymous	The activity near streams poster attempts to prove that there is currently no restoration of intermittent or perennial streams occurring. There are thousands of stream mitigation reports that have been submitted to the Corps of Engineers illustrating this is not the case. Section 404 requires mitigation to offset these types of impacts and adding another layer of regulation or agency that would require satisfaction is not technically feasible. OSM does not regulate Corps Permitting.	The FEIS recognizes that significant stream restoration activities are expected to occur under the No Action Alternative, i.e. without the SPR. The commenter is correct that OSMRE jurisdiction and authorities are separate from USACE jurisdiction and authorities. For additional discussion of the need for a nationwide rule please see the discussion contained within the rule preamble.
OSM-2010-0021-0029	Jim Adams	The information provided in reference to the current regulations illustrates that the USACE and other agencies are already regulating the same areas that are being proposed to be regulated by another entity. Section 303, 401, 402, and 404 of the CWA are already in place and functioning. This rule is merely adding to the existing burden. EPA has the opportunity to make comments on the permits and if the Corps requires an IP, these take years to process and there is very strict review. On Kentucky, the state also requires a stream restoration plan in the SMCRA permit. I don't think additional regulation is the answer. Seems that just working with the current agencies would make more sense than to completely rework SMCRA to fit. The other programs are much easier to adapt and make work than changing the SMCRA program. Work with the agencies to make a change, instead of trying to retrofit the entire existing SMCRA program.	Please see the discussion of the need for a nationwide rule contained within the rule preamble.

OSM-2010-0021-0029	Jim Adams	30 CFR Part 332 compensatory mitigation for losses of aquatic resources (See attached) under Section 404 already defines what the proposed rule is trying to add to the regulatory requirements. No modifications to the basic application, meaning, or intent of this part will be made without further joint rulemaking by the Secretary of the Army, acting through the Chief of Engineers and the Administrator of the Environmental Protection Agency, pursuant to the Administrative Procedure Act. Mitigation is already required in the exact same fashion that is being proposed. In addition, a conflict would occur between Section 404 and SMCRA if required to avoid "waters" when USACE does not require avoidance of "waters" but merely obtaining a permit first. As mentioned previously, Section 702 of SMCRA states it should not be construed as to replace the CWA. The proposal is absolutely attempting to supersede the CWA program and is therefore illegal and unlawful.	Please see the discussion of the need for a nationwide rule contained within the rule preamble.
OSM-2010-0021-0063	Virginia Coal and Energy Alliance	1. There is no basis or need for the SPR. 2.OSM failed to meaningfullt engage states and industry stakeholders. 3.SPR intrudes on the Clean Water Act (CWA). 4.SPR also interferes with the Endangered Species Act (ESA). 5. OSM's proposed change to Part 800 will disrupt the bonding market and make it virtually impossible for mining companies to meet the new financial guarantee requirements of the SPR. 6.OSM fails to differentiate underground mining, despite clear direction from Congress to do so. 7.The SPR will be prohibitively expensive to implement.	Please see the discussion of the need for a nationwide rule contained within the rule preamble.
OSM-2015-0002-0008	Natural Resource Partners LP	The Proposed Rule and accompanying analyses violate SMCRA by exceeding their authority as decided by court decision and as bounded by statute.	The rule and accompanying analyses are supported by SMCRA and based on sound science, as
OSM-2010-0021-0066	NMA	In recent years, there have been substantial advances in mining methods that minimize or avoid impacts. These approaches have not been addressed in the DEIS. Mining methods have evolved as technology has changed and as laws have been enacted to regulate the industry. For example, the three basic, modern approaches for underground mining should be included in separate alternatives. These include room-and-pillar, high-extraction retreat, and longwall. Current advancement in methods and technology are also absent from other sections of the DEIS,	Room and pillar, high-extraction retreat and longwall mining methods are evaluated in the FEIS through the model mines analysis. The surface disturbance related to these mining methods would be encompassed within the overall requirements of the rule and do not warrant identification as separate and unique from other methods in a separate alternative. Please refer to the Master Response on Model Mines Analysis for additional details about that

GENERAL

		including impacts assessment. These advances reflect the coal companies' compliance with federal and state regulations requiring approved mine plans (Bauer 2008).	analysis.
OSM-2010-0021-0048	North American Coal	We find it curious and disconcerting that OSMRE completely fails to emphasize, or even reference, actual evaluations of impacts, conducted by their own agency on an annual basis in all coal mining states, but instead relies on other "literature surveys and studies…"	OSMRE's annual evaluation reports routinely do not indicate problems with the states' implementation of their programs, however we disagree with the conclusion the commenters attempt to draw from this information, i.e., that our experience does not show that there is a problem that this rule is designed to address. OSMRE inspections and other oversight activities in primacy states, including the annual evaluation reports, focus on the success of state regulatory authorities in achieving compliance with the approved regulatory program for the state. OSMRE Directive REG-8, which establishes policy and procedures for the evaluation of state regulatory programs, specifies that the offsite impacts identified in annual evaluation reports do not include impacts from mining and reclamation that are not regulated or controlled by the state program. In other words, the annual evaluation reports generally do not identify or discuss situations in which the existing regulations provide inadequate protection. While Directive REG-8 provides discretionary authority for evaluations of impacts that are not prohibited by the regulatory program, that authority may be exercised only if both OSMRE and the state agree to do so, and if they are not characterized as offsite impacts. Historically, that discretionary authority has not been exercised. Thus, annual reports are of little assistance in assessing how the existing minimum federal standards that are incorporated into the approved state programs could be improved to better implement SMCRA.
OSM-2010-0021-0060	Ohio Department of Natural Resources	Chapter 4, Page 4-32, Figure 4.1-2, Forecasted Surface Coal Production by Region, Millions of Tons Produced, 2020 to 2040. The Appalachian Basin is not identified in the table forecasting coal production by surface coal mining	The commenter correctly identified an error in the legend for Exhibit 4.1-2. This has been fixed in the FEIS.

COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
			see Section IV.D. of the preamble to the final rule. The final rule strikes the appropriate balance between "protection of the environment and agricultural productivity and the Nation's need for coal as an essential source of energy," which section 102(f) of SMCRA lists as one of the purposes of SMCRA. Specifically, this final rule will better protect the water resources needed by current and future generations for drinking, recreation, and wildlife from the adverse effects of coal mining, while balancing protection of those resources with the Nation's energy needs.
OSM-2010-0021-0066	NMA	The alternatives considered in the DEIS are very narrow and do not adequately represent a reasonable range of alternatives that would minimize or avoid impacts to environmental resources. The differences between the alternatives are largely related to variations in the width of the stream buffers, differences in the definition of stream types, and variable allowances for mining through streams, mountaintop mining, and placement of materials in valley bottoms.	This comment, and other similar comments related to the range of alternatives, are addressed in the Master Response on Alternatives. Please see the Master Responses.
OSM-2010-0021-0066	NMA	In most instances, mining through streams, mountaintop mining, and placement of materials in valley bottoms are not permitted since they require the mining company to demonstrate prevention of material damage to the hydrologic balance. Hence mining through streams, mountaintop mining, and placement of materials in valley bottoms is effectively excluded under all the alternatives. Therefore, the difference between the alternatives is very small	This comment, and other similar comments related to the range of alternatives, are addressed in the Master Response on Alternatives. Please see the Master Responses.
OSM-2010-0021-0068	Earthjustice	OSMRE is wrong. The current regulations do not allow adverse effects on streams from filling or mining through streams. In fact, the current regulations plainly and unambiguously prohibit any mining activity within 100 feet of a stream that will have an adverse effect on the environmental resources of the stream [....]OSMRE's failure to correctly assess the no-action alternative infects its subsequent comparative analysis of the other alternatives. For example, OSMRE's conclusion that "all of the Action Alternatives (Alternatives 2 through 8) increase the stringency of the historic requirements that guide mining	The baseline for the analysis reflects the practical application of existing regulations absent the SPR. For additional information, please see Section IV.R. of the preamble to the final rule.

GENERAL			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		activities near streams and the placement of excess spoil and refuse," DEIS at 4-98, rests on the erroneous premise that the current regulations allow harmful mining activities in and near streams. Because the current regulations actually prohibit adverse effects on perennial and intermittent streams from mining activities within the buffer zone, OSMRE's assessment of alternatives 2 through 8 is erroneous and arbitrary.	
OSM-2010-0021-0068	Earthjustice	The DEIS analyzes nine alternatives, none of which corresponds to enforcement of current 30 C.F.R. § 816.57(a)(1). 2015 DEIS at ES-28. OSMRE says that alternative 2 is the most environmentally protective, but alternative 2 allows mining activities within the buffer zone—including coal mine waste disposal and mine-throughs—that will cause adverse effects on the environmental resources of intermittent streams. Alternative 2 is therefore less protective than current 30 C.F.R. § 816.57(a)(1), which prohibits adverse effects from such activities.	Thank you for your comment. Please refer to Master Response on Alternatives. Additionally, please refer to Section IV.R. of the preamble to the final rule.
OSM-2010-0021-0041	Anonymous	There should be another alternative analyzed for the rules that are related to the Clean Water Act and the Endangered Species Act, which would be supplemental interaction of OSMRE with other state and federal agencies with jurisdiction over the CWA and ESA. These agencies are already implementing most of what the rule proposes. The interaction would include discussion of the proposals, and how the agencies that actually have jurisdiction over the CWA and ESA can all work together to resolve the proposed concerns. It should also include a cost analysis comparison of the EIS instead of agency interaction to resolve the proposed issues	This and other similar comments expressing additional potential alternatives to be considered are addressed in the Master Response on Alternatives.
OSM-2010-0021-0049	Interstate Mining Compact Commission	The cooperating states have not been consulted during development of the current DEIS, as is evident by the application of a "one size fits all approach" versus consideration of state and regional differences to which the states are in the best position to speak. Because of its lack of commitment to engage the cooperating agencies, OSMRE failed to gather key insights as to how states implement their programs, what their current budgets (and budget shortfalls) are, and how state regulatory authorities will be impacted by some of OSMRE's proposals.	Please refer to Master Response on Cooperating Agencies.
OSM-2010-0021-0049	Interstate Mining	As for using only native species for reclamation, white, red,	We acknowledge that wildlife managers

	Compact Commission	and crimson clover, along with a few other non-invasive exotic species, are wonderful for most game species of wildlife. It would be poor habitat management to exclude them from reclamation projects.	frequently use non-native annual crops to supplement natural food sources, as was pointed out in several comments received on the proposed rule. However, we do not agree that the use of non-natives is necessary to successfully reclaim the site to the "Fish and wildlife habitat" land use category. This land use category is defined at 701.5 as "Fish and wildlife habitat. Land dedicated wholly or partially to the production, protection, or management of species of fish or wildlife." This definition does not specifically require a focus on game species to the detriment of other species and there are no other aspects of this land use category that would absolutely require the use of non-natives. Furthermore, there is no reason to believe that native species are not available to replace the use of the non- native species mentioned. Therefore, the use of non-natives use for this land use category is not necessary and does not merit an exception from the requirement for the use of native species.
OSM-2010-0021-0070	Luminant Mining Company LLC	OSMRE has not considered whether a regionally applicable rule, or a rule targeted to particular methods of mining (e.g., underground or mountaintop), would be a superior alternative, even though OSMRE is aware of the vast physical, social, and economic differences throughout the various U.S. coal-producing regions as evidenced by its discussion of each region separately throughout its impacts analysis	As discussed in the EIS (sections 2.1 on the Development of the Alternatives and 2.6 Alternatives Considered but Dismissed) and further described in the Master Response on Alternatives and in the preamble to the final rule, OSMRE did consider the unique aspects of underground and mountaintop mining, as well as regional differences.
OSM-2010-0021-0060	Ohio Department of Natural Resources	Chapter 4, Page 4-71, Stream Fills, Shank (2010) and Shank and Gebrelibanos (2013) "The more recent study estimates that 766 miles of perennial and intermittent streams were filled during the study period (1984 to 2012, which equates to 28 miles per year on average). It also shows a marked decrease in fill construction starting in approximately 2003. In 2012, stream miles filled decreased to approximately 18 miles in West Virginia for that year."The above statement on page 4-71 indicates that current mining regulations are being enforced and stream protection measures are working.	The reductions in impact noted in these studies are important but do not relieve the need for the proposed regulatory revisions. As shown in section 4.2.2.1 of the EIS through nationwide data for coal mining related permits authorizing activities under Section 404 of the Clean Water Act and Section 10 of the Rivers and Harbors Act, coal mining continues to require a significant amount of fill in streams and wetlands. The presented data is from the timeframe spanning from the beginning of 2012 to the end of 2014. The improved restoration of

COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		assessment. OSMRE must include all nine coal-bearing regions in the alternatives and impacts analysis, even those with low production. OSMRE also has an obligation under NEPA to examine the impact of the Proposed Rule on the American public in all states and localities where coal production occurs and contributes to the local and state economy.	as nine regions, versus the seven that OSMRE has used. However the regions are defined the analysis in the EIS captures areas that account for 95% of the coal production in the U.S. Capturing every area that is involved in the production of the remaining 5% would require the addition of a lot of material related to resources where relatively little production is occurring, and is therefore not consistent with our obligations under NEPA (specifically under 40 CFR 1502.15) to provide a succinct description of the areas affected by the alternatives under consideration, and to concentrate effort and attention on important issues. The inclusion of these areas is also not necessary to understand the effects of the alternatives.
OSM-2010-0021-0696	Murray Energy Corporation	Because each region and each specific area has different characteristics and different requirements, OSMRE should explain why a case-by-case analysis is not supported in the Proposed Rule. The Proposed Rule is too broad in its scope, using a one-size-fits-all approach for disparate mining regions and activities across the U.S. The Proposed Rule also does not distinguish between surface and underground mining. This overly-broad approach raises serious questions regarding implementation of the Proposed Rule and relevance of the Proposed Rule to different mining regions.	Please see the discussion of the need for a nationwide rule contained in section IV.D. of the preamble to the final rule.
OSM-2010-0021-0696	Murray Energy Corporation	OSMRE fails to devote any substantial discussion to the differences between underground and surface mining in the different regions and how these differences would impact the environmental consequences thereof in the regions. OSMRE provides considerable region-specific information that is largely unused or ignored in the alternatives analysis. OSMRE, instead, relies upon generalized and simplified assumptions and action alternative scenarios that, in many instances, are without relevance to one or more of the mining regions. For example, the chart of stream length by stream type in Table 3.5-1 reveals significant differences across regions regarding the occurrence of intermittent streams. Table 3.5-1 demonstrates that different mining regions have different ecological and hydrological function and form of streams and watersheds. However, OSMRE	OSMRE agrees that there are significant regional differences in mining methods as well as the natural resource conditions in which mining occurs. As described in Chapter 4 of the EIS, 13 model mines covering the seven major coal regions were designed to understand potential impacts to mining activities across regions and mine methods. Of these model mines, eight are for surface mines and five are for underground mines. Table 3.5-1 contains a summary of the lengths and percentages of intermittent and perennial streams for each coal resource region. This data is incorporated into the analysis of the number of streams that typically cross each mine site in each region. This analysis appears

GENERAL			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		ignores the information in Table 3.5-1 and applies a universal assumption of intermittent stream condition applicable to all mining regions in the action alternatives analysis. OSMRE's analysis must account for these cross regional variations.	in Section 4.2.1. Additional discussion of the methods used has been added to the FEIS in response to public comments.
OSM-2010-0021-0696	Murray Energy Corporation	"The affected environment for this DEIS includes any area where mineable coal occurs in the U.S. (Figure 3.1-1)." This is not a true statement. The DEIS is limited to only those areas where mineable coal exists and somewhat recent (2012) operations have occurred. For example, the DEIS specifically excluded evaluation of any data or impact from potential mineable coal in Northern Alaska, Washington, Oregon, Michigan, and parts of Nevada. Therefore, the alternatives in the DEIS do not adequately reflect the impact of the Proposed SPR on each of the coal producing regions of the U.S.	The regional boundaries as defined in the EIS capture the area that accounts for 95% of the current coal production in the U.S. Capturing every area that is involved in the production of the remaining 5%, or every area with coal resources without active production in the foreseeable future, is not necessary to understand the effects of the alternatives.
OSM-2010-0021-0696	Murray Energy Corporation	The fact that the geographic scope (which defines the action area or area of impact) is likely to be over-inclusive demonstrates and confirms that the impacts associated with mining are also over-inclusive and therefore, overestimated. This is a significant issue, and the geographic scope should be reanalyzed. CEQ included geographic scope as part of the definition for "significance."	The study area for the EIS is intended to encompass all areas that may be mineable in the foreseeable future within the time period for the analysis. The methodology for identifying the areas is described in Chapter 4 of the EIS. The analysis is intended to be conservative to capture the universe of potential effects.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.1.1.1, p. 4-32, Figure 4.1-2The legend on the right side of the figure omits the Appalachian Basin at the bottom (assuming the red-and-white pattern is for Appalachia as it is in Figure 4.1-3).	Thank you for your comment. There was a typo on the legend, which we have now resolved.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.2.1, p. 4-49, second paragraph OSMRE's statements do not recognize that there are a number of reasons that riparian zones do not or cannot occur along specific stream reaches. Particularly in the west, streams that are incised or on bedrock may not have soil or hydrologic characteristics that support a riparian zone of a given width (e.g., 100 ft.).	The comment refers to text that is explaining the function of vegetated buffers and existing requirements for these buffers within our regulations as part of the discussion of the impacts to water resources from coal mining under the no action alternative. The text acknowledges that the RA can grant an exception to this requirement and routinely do so. Circumstances where the site specific conditions in the riparian zone do not allow for a 100-foot buffer would be an example of where the RA would grant such an exception. Therefore no change is necessary to the existing text.

OSM-2010-0021-0696	Murray Energy Corporation	Effects of Action Alternatives on Coal Production Section 4.1.4, p. 4-42, Table 4.1-5 If the differences between the listed totals and the results from adding the individual numbers are attributable to rounding, there should be a note to that effect. Otherwise there are incorrect sums.	The commenter is correct; the totals may not sum accurately due to rounding. A note has been added stating this.
OSM-2010-0021-0696	Murray Energy Corporation	Effects of the Current Regulatory Environment (the No Action Alternative) Section 4.2.2.1, p. 4-88, last paragraph None of the references that are provided as the basis for biological impacts in this section identify impacts from post-1983 western mines. Transferring conclusions from different geographic regions without backup of site-specific regional references is not supportable as "best available science."	OSMRE acknowledges that much of the research on understanding downstream effects of coal mining has been conducted in Appalachia. The history and extent of mining in the Appalachian Basin makes it the subject in the majority of the water quality studies (e.g., Lindberg et al., 2011, Merriam et al., 2011, Petty et al., 2010, Pond et al., 2008, Fulk et al., 2003). In addition, authors have also noted that due to the arid climate and high mineralization of stream water, analyses of this type are more difficult in western regions. Though limited, literature in other regions indicates similar downstream impacts despite obvious difference in geography. To account for these differences, model mines were developed to represent geography, coal production, and other environmental factors of each coal mining region.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.3.1, p. 4-137, second bullet Alternatives 2, 3, 4, 5, 7, and 8 (Preferred) require—... Salvage and redistribution of topsoil, subsoil, and other suitable materials (not just topsoil as in the No Action Alternative) necessary to create the root zone needed to support revegetation (especially trees) and restore premining capability. This statement suggests that all topsoil is of suitable quality to be salvaged and redistributed during reclamation activities. In fact, soils vary significantly with respect to pH, electrical conductivity (EC), particle size, sodium adsorption ratio (SAR), and available water capacity. Soils with a pH <5.5 or >9.0, soils with an EC >15 millisiemens per centimeter (mS/cm) 25° Celsius, soils with a gravel or very coarse sand texture, or clay soils with a SAR>14 may be unsuitable for reclamation.	As clarified in the preamble to the final rule, OSMRE agrees that determinations on the redistribution of soil materials should be based on site-specific information and the experience of local experts, and the rule does not depart from this perspective. Although the rule requires the regulatory authority to make additional determinations, the regulatory authority remains the ultimate decision maker on the handling and replacement of soils, and its decisions will be based on local, site-specific conditions.

10201	Pennsylvania Watersheds	mapping provides “a valid, consistent source of the location and size of wetlands within all of the coal regions.” (p. 3-322) That unsupported and conclusory statement (1) is not true universally and (2) most certainly has not been the case in Pennsylvania, where more than half of palustrine forested wetlands are omitted by the NWI mapping and statistics....NWI maps accurately depict open waters (such as lakes and ponds) as well as some larger streams and wetlands. They are based on high-altitude aerial photographs which frequently cannot discern hydric soil conditions or localized, seasonal wetness. NWI maps in Pennsylvania typically omit small wetlands and wetlands beneath deciduous forest canopy. In very few spots has NWI mapping ever been field-verified. The NWI maps are only approximations of the actual extent of the most conspicuous wetlands in a given area, and they never were intended to be accurate --- or used --- for site-specific regulatory purposes such as coal mine planning and review.We recommend strongly that the NWI maps not be relied upon, but instead that all wetlands within the Permit Area and Adjacent Area be field-delineated, mapped, and field-checked by the Corps of Engineers. We believe this procedure is best incorporated in the Rule by inserting a new definition of wetlands, as discussed above.	comment. OSMRE agrees that NWI data is insufficient for site-specific determinations regarding the presence or absence of wetlands, and certainly does not meet the standards for field delineation of jurisdictional wetlands. Section 779.19(a)(3) of the final rule requires identification, description and mapping and delineation of all wetlands to satisfy identification requirements of vegetation within the permit application. However NWI, as used here in the EIS, is valuable for description of wetlands at a planning level across larger scale areas. As discussed in the preamble to the final rule, we have not added a definition of “wetlands” because 40 CFR 230.3(o)(3)(iv) sufficiently conveys this information and it is part of the guidelines that have been developed by the Administrator of the Environmental Protection Agency in conjunction with the Secretary of the Army acting through the Chief of Engineers under section 404(b)(1) of the Clean Water Act.
OSM-2010-0021-0696	Murray Energy Corporation	Need to Apply Current Information, Technology, and Methods Section 1.1.4, p. 1-16 "More traditional approaches to restoration of AOC have created large reclaimed acreages that resemble landscapes of agricultural fields, urban recreational parks, or construction fill sites such as large dam embankments, spillways, or waterway diversions." This statement is a generalization that is neither relevant nor appropriate.	No change is necessary. The text is purposefully a generalization of the results that are achieved under existing regulations for AOC restoration that are general, subjective, and lacking in specificity. As discussed on page 1-14 of the DEIS, this has resulted in postmining surface configurations that are significantly flatter than the premining configuration; that lack many of the landform features found prior to mining; and that have significantly altered drainage patters and stream characteristics and functions. The text on page 1-16 are examples to visualize these results and are therefore relevant to the discussion of the need to improve the objective standards.

OSM-2010-0021-0696	Murray Energy Corporation	Surface Effects of Underground Mining - Subsidence MechanismsFigure 3.1-8, p. 3-17The text accompanying this figure correctly states that surface subsidence is normally about two-thirds of the thickness of the coal seam being mined and can range from near zero to the full thickness of the coal seam. This figure shows a subsidence depth of nearly double the thickness of the coal seam being mined. This is misleading. The figure should be edited to depict a plausible subsidence scenario, or the subsidence depth in the figure should be clearly labeled as vertically exaggerated to illustrate the concept of subsidence.	Thank you for the comment. The text supporting the figure now clarifies that the vertical dimension has been exaggerated to effectively demonstrate the concept of subsidence but is not meant to be a scale accurate depiction.
OSM-2010-0021-0696	Murray Energy Corporation	Topography Section 3.4, p. 3-104 Moreover, the photographs included in Section 3.4 do not appear to represent typical mining situations; the DEIS does not provide sufficient context regarding the apparently unusual environmental conditions depicted. If the pictures depict an unusual situation (e.g., associated with a particularly large storm), then OSMRE should remove the pictures and the text should be modified to reflect common or typical environmental conditions. Finally, these photographs serve no other purpose except to bias readers with respect to the hazards associated with mining; they provide no useful technical information to inform the action alternatives analysis.	Thank you for the comment. The pictures are used to depict unusual or abnormal events that occur coincidentally with mining, and this implication is already clear in the text. The context is sufficiently clear, and we have not changed the text in response to this comment.
OSM-2010-0021-0696	Murray Energy Corporation	Groundwater Usage Overview Section 3.5.2.2, p. 3-131 Both definitions for groundwater here differ from OSMRE's proposed definition of groundwater in the Proposed Rule.	No change is necessary in response to this comment. This section provides information on the current affected environment and therefore uses the definition from existing regulations.
OSM-2010-0021-0696	Murray Energy Corporation	Groundwater Usage OverviewSection 3.5.2.2, p. 3-131"As defined in the federal regulations (30 CFR 701.5), groundwater is "subsurface water that fills available openings in rock or soil materials to the extent that they are considered water saturated. " A USGS report (USGS, 2000b) states that groundwater "... provides drinking water to urban and rural communities, supports irrigation and industry, sustains the flow of streams and rivers, and maintains riparian and wetland ecosystems. In many areas of the Nation, the future sustainability of groundwater resources is at risk from overuse and contamination. Because groundwater systems typically respond slowly to	The definition of groundwater has been changed in the rule. Please refer to section 701.5 of the rule.

GENERAL			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		human actions, a long-term perspective is needed to manage this valuable resource. "The USGS dictionary defines groundwater as: *(1) water that flows or seeps downward and saturates soil or rock, supplying springs and wells. The upper surface of the saturate zone is called the water table. (2) Water stored underground in rock crevices and in the pores of geologic materials that make up the Earth's crust. (USGS, 2015)* There is an important technical distinction between this USGS definition and the definitions quoted in the DEIS. The USGS definition of groundwater focuses on flowing water, but also includes non-flowing water that may be stored in clay or other geologic material. OSMRE should clarify the context in which it proposes to monitor groundwater, and specify that groundwater is defined with respect to aquifers and not the presence of soil moisture and water captured in the subsurface and unavailable for use.	
OSM-2010-0021-0696	Murray Energy Corporation	Surface Water Overview Section 3.5.2.3, p. 3-132 The proposed definitions of "insulated" and "perched" streams appear to be the same. If OSMRE intends that these terms be distinct, it should propose distinct definitions for each term. It is important to clarify these terms because they are used throughout the DEIS.	The referenced text provides definitions quoted from a third party classification system. These terms are not used throughout the DEIS; the term "perched" is used in several other instances within the text of the DEIS but is used in the context of perched groundwater and not in reference to the concept of perched streams as used in the classification system being discussed in the text referenced by this comment.
OSM-2010-0021-0696	Murray Energy Corporation	Greenhouse Gas Permitting for Stationary SourcesSection 3.6.1.3, p. 3-208. The requirement to address greenhouse gasses through the PSD permitting process in accordance with the Tailoring Rule was significantly curtailed by the Supreme Court in their decision in Utility Air Regulatory Group v. U.S. EPA, 134 S. Ct. 2427 (2014), which concluded that U.S. EPA may not treat greenhouse gasses as an air pollutant for purposes of determining whether a source is a major source required to obtain a PSD or Title V permit. On June 25, 2014, U.S. EPA subsequently issued a clarifying memorandum stating they will no longer require permits for "step 2" sources (i.e., sources that triggered permitting requirements based solely on their greenhouse gas emissions). OSMRE should update this section to provide a more accurate and current regulatory context of greenhouse gas emission regulation under the CAA.	The information in Section 3.6.1.3 has been updated to reflect the current status of the Greenhouse Gas Tailoring Rule and an additional Section 3.6.1.4 “Climate Change and Clean Power Plan” was added.

OSM-2010-0021-0696	Murray Energy Corporation	Air Quality, Greenhouse Gas Emissions, and Climate Change Section 3.6.2.5, Figure 3.6-10, p. 3-227 The title and description of Figure 3.6-10 indicates that the figure includes Class I areas in the Northern Rocky Mountains and Great Plains Region. These Class I areas are listed in a table appearing on pages 3-225 and 3-226. The map in Figure 3.6-10 does not include these Class I areas. This figure should be updated to accurately reflect the text of this section.	Thank you for the comment. Figures throughout Section 3.6 have been updated for the FEIS.
OSM-2010-0021-0696	Murray Energy Corporation	*Section 4.5, p. 4-331* OSMRE failed to include a summary discussion of why Alternative 8 is preferred. Without a quantified discussion of its selection, stakeholders are unable to provide comment. The body of the DEIS has no conclusory chapter.	Thank you for the comment. The Preferred Alternative is the proposed rule itself. As discussed in the Department of the Interior (DOI) NEPA regulations (43 CFR 46.420(d)) our Preferred Alternative, as represented in the final rule with supporting rationale provided in the preamble, is the one which we believe would best accomplish the purpose and need of the Preferred Alternative while fulfilling our statutory mission and responsibilities, while giving consideration to economic, environmental, technical and other factors.
OSM-2010-0021-0696	Murray Energy Corporation	Section B.2, p. B-l OSMRE should clarify if it is endorsing these stream bioassessment methods and clarify the level of biological organization best suited for assessment of mine-related impacts. OSMRE should confirm that it is suggesting benthic macroinvertebrates as a target indicator species.	Please refer to the discussion of biological baseline and monitoring data requirements in the preamble to the final rule.
OSM-2010-0021-0696	Murray Energy Corporation	*Section C.I, p. C-l, first paragraphLotic or flowing aquatic systems are common landscape features in areas where coal mining is conducted. Lotic systems include creeks, springs, streams, rivers, etc. This section will discuss the various lotic systems and their features and functions within the study area The descriptions provided here in this section are based on the generally accepted physical and ecological characteristics that define these systems; these definitions will not necessarily be identical to the regulatory definitions used in SMCRA the CWA or elsewhere.* OSMRE should clarify why some definitions in Appendix C are not necessarily identical to the regulatory definitions likely to be imposed.	As explained in the EIS the descriptions provided here in this section are based on the generally accepted physical and ecological characteristics that define these systems; these definitions will not necessarily be identical to the regulatory definitions used in SMCRA the CWA or elsewhere. Definitions used to describe streams in general to ensure understanding of the concept on the part of the EIS reader would need to convey different information than those developed to ensure clarity in which systems fell under any certain category per the regulation.
OSM-2010-0021-0696	Murray Energy	*Section C.I.16, p. C-18, first paragraph*	. The reference to Palmer (2009) was in error

GENERAL			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
	Corporation	*Although fish tend to occupy larger streams, multiple species can use ephemeral and intermittent streams as habitat.* OSMRE should provide a reference for this statement. Meyer et al. (2007) and Palmer (2009) do not discuss fish using ephemeral streams.	and should have referred to Bernhardt and Palmer 2011 which discusses the importance of small stream habitats to fish diversity and population size on page 41. Please also refer to Section "Biological Diversity in Small Streams" subsection "Fish" on Pages 90 through 93 in the Meyer et. 2007 reference.
OSM-2010-0021-0696	Murray Energy Corporation	Table F-l Species List, p. F-4 OSMRE should change the "Mollusks" category to "Mussels," and associate the snail, Triodopsis platysayoides, with the other "Snails" on p. F-7.	The final Biological Assessment (see Appendix F) contains the final species list developed as a result of ESA Section 7 consultation for the Stream Protection Rule. This list reflects several species status changes that occurred following the DEIS publication. The mollusk category has been retained, as there are mussels and snails that fall into this category. The final list places the Triodopsis platysayoides snail within the "terrestrial snail" guild within the category of mollusks.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.1.4, p. 4-72, "Streams degraded downstream of mining operations" bullet "While state CWA section 303(d) water quality reports routinely identify coal mining as a pollution source, these data are not compiled at the regional level." Most 303(d) listed streams with mining impacts in the western U.S. are from historical mines not those currently permitted under SMCRA.	No changes are necessary in response to this comment. The text is within a discussion of the challenges associated with using various data sources including the 303(d) listings to compare the Action Alternatives against the no action alternative; the comment (if correct) supports this discussion.
OSM-2010-0021-0070	Luminant Mining Company LLC	Similarly, the DEIS fails to consider the impacts of the Enhanced Coordination Process and U.S. EPA's guidance on permitting under the Clean Water Act, both upheld by the D.C. Circuit in 2014.82 These actions tightened the requirements for obtaining permits for surface coal mining in Appalachia. In addition, the DEIS does not consider the impacts of U.S. EPA's recent use of the Clean Water Act veto provision.	Enhanced Coordination Procedures (ECP) is considered part of the regulatory baseline for this rule. To efficiently process a backlog of pending Section 404 permits, U.S. EPA and the USACE issued ECP on June 11, 2009. EPA also developed guidance for review of applications for permits for Appalachian surface coal mining operations under the CWA (U.S. EPA Permitting Guidance), which was finalized on July 21, 2011. This guidance was intended to clarify U.S. EPA's roles and expectations in permitting surface coal mining operations under section 402 and 404 of the CWA, and to "assure more consistent, effective, and timely review of Appalachian surface coal mining operations with respect to provisions of the CWA, the National Environmental Policy Act, and Environmental

GENERAL			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
			Justice Executive Order, as implemented by USEPA and USACE." This guidance included protective actions that went beyond the 2008 SBZ rule with regard to excess spoil placed in streams (i.e., these requirements imposed further requirements on mine design). The U.S. District Court for the District of Columbia set aside the U.S. EPA Permitting Guidance in July 2012. However, in its July 31, 2014 decision related to the ECP, the U.S. Court of Appeals for the D.C. Circuit also held that the U.S. EPA Permitting Guidance was not "a final agency action subject to pre-enforcement review." Because this appellate decision relied on the fact that the U.S. EPA Permitting Guidance did not "impose any obligations or prohibitions on regulated entities [and] State permitting authorities 'are free to ignore it[,]'" the EIS does not consider the U.S. EPA Permitting Guidance as part of the regulatory baseline for this rule. However, the analysis does consider the U.S. EPA's veto provision. U.S. EPA exercised its veto authority under section 404(c) of the Clean Water Act in 2009 by retroactively revoking a permit issued by the USACE in 2007 to allow the filling of streams in connection with a large surface coal mining operation in West Virginia. The company challenged the veto and won at the District Court level, but the U.S. Court of Appeals for the District of Columbia Circuit reversed that decision and upheld the veto on April 23, 2013 (Mingo Logan Coal Company v. U.S. Envtl. Prot. Agency, Civil Action No. 12-5150; 2013 U.S. App. LEXIS 8121 (D.C. Cir. April 23, 2013)). Mingo Logan appealed to the United States Supreme Court, who declined to hear the case in March, 2014 (714 F. 3d 608). On September 30, 2014, the D.C. District Court ruled in favor of U.S. EPA on the issues remanded to it by the D.C. Court of Appeals (D.C. Cir. September 30, 2014). Language about these regulations and how they were incorporated in the analysis has been

			added to the EIS.
OSM-2010-0021-0696	Murray Energy Corporation	The proposed increased monitoring would have little effect in some western jurisdictions such as Montana, where this level of monitoring is already substantially realized (see Mont. Admin. R. 17.24.3048.	No changes are necessary in response to this comment. Benefits were determined through the model mine analysis, which used actual permit data from current mines to design and analyze thirteen "representative" model mining operations, which are categorized by region and size (tons of coal produced annually). The model mines represent actual operations that have been permitted and implemented under existing regulations at the state and federal level and therefore already take into account existing protections and benefits of existing regulations in the manner in which they are actually applied.
OSM-2010-0021-0696	Murray Energy Corporation	OSMRE must clarify what is meant by "isolating the effect of individual mining operations." This language implies that water resources will be affected by mining operations, and potentially at multiple mining operations within a watershed or area where there could be an additive effect (hence the need for "isolation of effect of individual mining operations"). The language is vague and does not reflect inherent differences between surface mining versus underground mining.	Thank you for your comment in regards to the text on page 4-57 of the EIS that states "Some of the rule elements in Table 4.2.1-1 have indirect implications for surface water and groundwater quality that may not be readily apparent. For example, Action Alternatives that require expanded baseline monitoring will help authorities assess the premining quality of water resources and better isolate the effect of individual mining operations." The text means that additional baseline monitoring will assist in determining whether any particular mine is the source of an observed problem during monitoring, i.e. that the data will allow "isolating" the actual source of the problem for identification. To the extent that the wording of the DEIS caused confusion, the text has been clarified in the FEIS.
	Wyoming Department of Environmental Quality	DEIS Section 5.2 WDEQ and the Office of Surface Mining entered into a Memorandum of Understanding (MOU) dated August 25, 2010 wherein WDEQ agreed to serve as a cooperating agency for the development of the Stream Protection Rule DEIS. Wyoming agencies have served as cooperating agencies many times with the Department of Interior and the Department of Agriculture. WDEQ did not enter into the MOU lightly or without an understanding of the commitment	Please refer to the Master Response on Cooperating Agency involvement and Section IV.B. of the preamble to the final rule.

GENERAL			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		of staff and resources required to best serve the development process. WDEQ was only provided limited opportunities with unreasonably short review times to review the drafts of three chapters in late 2010 (review period of only September and October) and early 2011 (review period of only January). OSMRE did not engage WDEQ after those reviews. The State of Wyoming and WDEQ sent several letters to the OSMRE Director on several occasions (See Attachment 4) reiterating the request by the State of Wyoming and WDEQ to be engaged by OSMRE in that process. It must be assumed that those requests were all denied since OSMRE failed to engage WDEQ further much less respond to most of those requests. The description of the cooperating agency review process as included in the DEIS is not an accurate representation of that process or how states were consulted. Any perception that WDEQ was involved or consulted by OSMRE is incorrect. The failure to honor the terms of the MOU with WDEQ and the other cooperating agencies is clearly reflected in the lack of recognition of the best practices and technical expertise that exists at the delegated regulatory authorities. OSMRE should withdraw the Proposed Rule and re-engage the cooperating agencies.	
OSM-2010-0021-0050	Wyoming Department of Environmental Quality	DEIS Section 5.2The DEIS provides information regarding the participation by Federal and State agencies in the process as Cooperating Agencies. WDEQ takes exception to how the relationship between OSMRE and WDEQ was presented. The narrative in the DEIS would lead one to believe that there had been robust coordination with WDEQ, similar to what OSMRE stated was conducted with U.S. EPA and U.S. FWS. That was clearly not the case. Even the reviews of the three chapters referenced in the narrative had incredibly short review times, making meaningful input from WDEQ impossible. For example, WDEQ was given 7.5 working days to review Chapter 4, which contained 278 pages. A January 18, 2011 letter from WDEQ Director John Corra to Mr. Paul Ehret of OSMRE requested a 30-day review of Chapter 4. As stated by a subsequent January 26, 2011 letter from WDEQ Director John Corra to Mr. Paul Ehret of OSM, the request was not responded to so WDEQ only had time to provide general comments on limited sections of Chapter 4. After the review of the third chapter in January 2011, OSMRE totally disengaged from cooperation....An absence of any	Please refer to the Master response on Cooperating Agency involvement, updates within Chapter 5, and Section IV.B. of the preamble to the final rule.

GENERAL			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		opportunities for review or input into the development of the subsequent DEIS does not under any measure satisfy cooperating agency principles. The failure by OSMRE to even respond to letters regarding the cooperating agency process is an appalling failure to comply with the cooperating agency MOU, much less the principles of cooperating agency processes. It is confusing at best why OSMRE so casually dismissed the years of expertise and best practices of the Regulatory Agencies, including Wyoming, in the development of a Proposed Rule of this size, scope, and rigidity that WDEQ will be expected to implement.	
OSM-2010-0021-0050	Wyoming Department of Environmental Quality	DEIS Page 5.3 OSMRE clearly admits that it has not engaged the states in development of the Proposed Rule and the DEIS over the past 5 years, despite significant changes in the DEIS from the Preliminary DEIS. Although OSMRE may intend to work with cooperating agencies in the future, not allowing states to participate as cooperating agencies in the development of the Proposed Rule and DEIS after states had accepted cooperating agency status is a clear violation of NEPA as well as the intent of SMCRA. The Proposed Rule should be withdrawn.	OSMRE has complied with both NEPA and SMCRA. See the Master response on Cooperating Agency involvement, Chapter 5 of the EIS, and Section IV.B. of the preamble to the final rule for a detailed discussion of the coordination and outreach between OSMRE and the cooperating agencies.
OSM-2010-0021-0056	Utah Mining Association	The SPR will not provide regulatory certainty to industry. In fact, the DEIS appears to contradict the SPR. The DEIS seems to assume that only proposed mines that will result in permanent adverse impacts will not be permitted. The SPR would appear to preclude the permitting of mines even where there are temporary impacts. Such discrepancies result in the agency potentially underestimating impacts in the DEIS that do not reflect the actual text of the SPR.	The analysis of the DEIS and the contents of the rule are not in conflict, and the DEIS does not underestimate impacts in comparison to the actual text of the rule. OSMRE has clarified in the final rule that not all of impacts would necessarily rise to the level of material damage to the hydrologic balance outside the permit area, especially ones of a temporary nature.
OSM-2010-0021-0050	Wyoming Department of Environmental Quality	The WDEQ is disappointed in the quality of the draft documents that have been released for review. Information and statements do not appear to be consistent across the three documents, resulting in difficulty in determining the intent or basis for much that is included in the Proposed Rule. This results in increased difficulty for those reviewing and attempting to analyze the three documents. Numerous scientific and non-scientific studies and reports are referenced to support the Proposed Rule. Those referenced documents are often detailed and highly technical. It was impossible to review the Proposed Rule, DEIS and DRIA as well as the referenced studies with the review time	The stream protection rule has been the subject of robust public involvement, starting in 2009. During that year, we published an advance notice of proposed rulemaking, conducted 15 stakeholder outreach meetings, held nine public scoping meetings, and provided two public comment periods totaling 76 days on scoping for the DEIS. The scoping process generated over 20,500 comments, including input from state regulatory authorities. On July 16, 2015, we announced that the proposed rule, DEIS, and Draft RIA were

GENERAL			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		allowed. That has resulted in an incomplete review. The WDEQ has spent over 1,000 man-hours reviewing the Proposed Rule and the associated documents during the review period. Despite our best efforts, we are not able to complete the review and the review remains incomplete. Topics like multimetric bioassessment are of a huge concern for us. Because of the limited time available, we were not able to do a robust review of the DEIS, the literature cited in the EIS and several other technical topics or the DRIA.	available for review at www.regulations.gov, on our website (www.osmre.gov), and at selected OSMRE offices. On July 17, 2015, we published a notice in the Federal Register announcing the availability of the DEIS for the proposed rule. See 80 FR 42535-42536. The notice reiterated that the DEIS was available for review at www.regulations.gov, www.osmre.gov, and the OSMRE offices listed in the notice. The comment period for the DEIS was originally scheduled to close on September 15, 2015. On July 27, 2015, we also published the proposed stream protection rule in the Federal Register. See 80 FR 44436-44698. That document reiterated that the proposed rule, DEIS, and Draft RIA were available for review at www.regulations.gov, www.osmre.gov, and the OSMRE offices listed in the notice. The comment period for the proposed rule and Draft RIA was originally scheduled to close on September 25, 2015. In response to requests for additional time to review and prepare comments on all three documents, we extended the comment period for the proposed rule, DEIS, and draft regulatory impact analysis through October 26, 2015. See 80 FR 54590-54591 (Sept. 10, 2015). Interested parties, therefore, received a total of 102 days to review the proposed rule and supporting documents. During that time, we also held six public hearings in Colorado, Kentucky, Missouri, Pennsylvania, Virginia, and West Virginia. We received approximately 95,000 comments from all sources on the proposed rule, DEIS, and Draft RIA. The proposed rule, DEIS, and Draft RIA included citations to references that we relied upon in developing those documents. These reference citations were available from the time of publication of the proposed rule, DEIS, and the Draft RIA in the Federal Register. We used these references in discussing both specific components of the rule and our analysis, as well

GENERAL			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
			as for support of our discussion on more general concepts. We did not receive any requests for copies of these references during the comment period. However, in response to language that Congress included in a report accompanying the Consolidated Appropriations Act of 2016, Pub. L. 114-113, we placed all publicly-available references on www.regulations.gov. Copyright-protected materials are easily obtainable through state or university libraries or the publisher. We were not able to provide copyright-protected items to requesters directly because doing so might violate copyright laws. We also scheduled meetings of OSMRE and state technical personnel to discuss the scientific studies and other reference documents on two dates (April 14 and 21, 2016). The meetings were held simultaneously in Denver, Colorado; Alton, Illinois; and Pittsburgh, Pennsylvania. Staff from six state regulatory authorities participated in the meeting on April 14, 2016, and staff from five state regulatory authorities participated in the meeting on April 21, 2016. The comment period we provided fully complies with the Administrative Procedure Act, 5 U.S.C. 553, which does not set a minimum public comment period for a proposed rule. We also exceeded the 60-day minimum comment period recommended by Section 6(a)(1) of Executive Order 12866 for meaningful public participation. This time is comparable to the comment periods for similar regulations that we have issued in the past. For example, the now-vacated 2008 stream buffer zone rule was subject to a 90-day comment period, while the comment period for the 1978 proposed rule containing most of the original permanent regulatory program regulations was 71 days. It is also noteworthy that many commenters, primarily environmental groups, opposed our 30-day extension of the comment period. They maintained that 60 days was sufficient to review the materials and provide meaningful comment.

GENERAL			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
			These and other commenters, including state regulatory authorities, were able to provide extensive, detailed, meaningful comments on the proposed rule in the comment period provided.
OSM-2010-0021-0050	Wyoming Department of Environmental Quality	Wyoming, throughout the history of the coal mining regulatory program under the Surface Mining Control and Reclamation Act (SMCRA), has developed best practices that are suited to our climate, natural hydrologic conditions, topography and geography. Nowhere in the process of preparing these documents did OSMRE request from Wyoming those best practices so they could be considered in the development of the three documents. The failure to request or consider state specific best practices has resulted in incorrect assumptions many requirements in the Proposed Rule that are impractical or have limited, if any, benefit in Wyoming. The Proposed Rule should be retracted and redrafted with consideration of Wyoming's best practices to address and reflect state and regional best practices.	OSMRE does not disagree that advances in reclamation have been achieved and are reflected in certain states best practices, for example states that require the use of native plantings. However the existing regulations are now insufficient because they did not require these best practices. To the extent thatadvances have been made an incorporated into ongoing mining practices, OSMRE has incorporated these advances in reclamation under the No Action Alternative. Additionally, the comment fails to recognize that requiring a best practice that a state has already implemented does not impose any additional burden on that state.
OSM-2010-0021-0050	Wyoming Department of Environmental Quality	The DEIS attempts to address the basis and need for the massive sweeping changes proposed in the Proposed Rule. It does not, however, describe in any detail what is not being done correctly in Wyoming or how WDEQ has erred in the role as Regulatory Authority as delegated under SMCRA. The DEIS does not list program deficiencies, instances where OSMRE has required corrective action, instances where cumulative hydrologic impact assessments (CHIA's) have not been done correctly or any other basis for the major changes and imposition of such strict and inflexible requirements.	While it is true that the DEIS does not list specific deficiencies or errors in the current state SMCRA regulatory programs this is not indicative of a lack of need for the Proposed Action. OSMRE's annual evaluation reports routinely do not indicate problems with the states' implementation of their programs, however we disagree with the conclusion the commenters attempt to draw from this information, i.e., that our experience does not show that there is a problem that this rule is designed to address. OSMRE inspections and other oversight activities in primacy states, including the annual evaluation reports, focus on the success of state regulatory authorities in achieving compliance with the approved regulatory program for the state. OSMRE Directive REG-8, which establishes policy and procedures for the evaluation of state regulatory programs, specifies that the offsite impacts identified in annual evaluation reports do not include impacts from mining and

GENERAL			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
			reclamation that are not regulated or controlled by the state program. In other words, the annual evaluation reports generally do not identify or discuss situations in which the existing regulations provide inadequate protection. While Directive REG-8 provides discretionary authority for evaluations of impacts that are not prohibited by the regulatory program, that authority may be exercised only if both OSMRE and the state agree to do so, and if they are not characterized as offsite impacts. Historically, that discretionary authority has not been exercised. Thus, annual reports are of little assistance in assessing how the existing minimum federal standards that are incorporated into the approved state programs could be improved to better implement SMCRA. Part II of the final rule preamble summarizes the water quality and land reclamation problems that developed under the previous rules. In addition, speakers at the public hearings described their experiences with dewatering of streams as a result of subsidence from underground mining operations.
OSM-2010-0021-0696	Murray Energy Corporation	*Section 4.2.3.4, P-4-146* *The operator would be required to redistribute soils in a manner that limits compaction and provides optimal rooting depth to support the approved plan for revegetation and reforestation.* This statement assumes soil permeability should be promoted on all sites. Soil infiltration should not be extensively promoted on sites where seepage through cover materials has the potential to increase acid mine drainage.	The commenter assumes that the requirements to redistribute soil supersede requirements under section 816.38 and allow increased seepage and mine drainage. The commenter's assumption is incorrect. All acid-forming materials and toxic materials must be "treated or buried and compacted or otherwise disposed of in a manner designed to prevent contamination of ground or surface waters." See SMCRA Section 515(b)(14).Additionally, "overburden or spoil shall be shaped and graded in such a way as to prevent slides, erosion, and water pollution." See SMCRA Section 515(b)(3). These requirements persist in addition to the requirements to redistribute soil. Accordingly, commenter's concern is unfounded.
OSM-2010-0021-0696	Murray Energy	Action Alternatives and Potential Effects on Biological	In the final version of the rule (the Preferred

	Corporation	Resources Section 4.2.2.2, pp. 4-97 to 4-98, last bullet "Alternatives 3, 4, 5, 6, and 8 (Preferred) would implement additional protections to all streams, including requiring that at least some ephemeral streams be restored inform." Pages ES-19 and 2-35 state that there has to be a 100-ft buffer on each side of every perennial, intermittent, and ephemeral stream following completion of mining activities. OSMRE fails to specify the characteristics that will prompt restoration of some ephemeral streams, and not others.	Alternative) OSMRE has added new section 817.56 which sets out the requirements for ephemeral streams. These include requirements that are counterparts to those for intermittent and perennial streams such as requirements to comply with the Clean Water Act, establish a postmining drainage pattern and stream channel configuration that is consistent with the approved permit, and establish a 100-foot streamside vegetative corridor that complies with the standards in 817.57(d)(1)(iv) through (4) if activities are conducted through an ephemeral stream.
NA	EPA	Page 4-46, second-to-last paragraph, last sentence: Suggest noting that, in addition to NWP 21, current NWPs 49 and 50 also authorize coal mining related activities - Coal Re-mining (NWP 49) and Underground Coal Mining (NWP 50).	The text has been updated to include NWP 49 and NWP 50 permits for surface coal remining and underground mining, respectively.
OSM-2010-0021-0696	Murray Energy Corporation	Impacts of the Alternatives Section ES.8, p. ES-42 It is unclear how implementing the Preferred Alternative would improve the permitting process. It appears the added requirements of the Proposed SPR would make the permitting process more complicated and increase the time and associated cost of the permitting process both for the regulators and the regulated community.	The permitting process would improve under the Preferred Alternative because it would be more effective in ensuring that the operation will be conducted in compliance with all requirements. The proposed permitting process would require additional sampling, evaluation, and characterization of the proposed permit area. This information would allow the regulatory authority to more easily determine whether mine plans are designed in accordance with the regulatory program and would also improve the assessment of the mine operation's compliance with the permit.
OSM-2010-0021-0066	NMA	Most of the alternatives considered require that 12 evenly spaced samples are collected from a consecutive 12-month period in all intermittent and perennial streams. Since intermittent streams do not flow for 12 months in a year, this is either not possible (if the intent was monthly sampling) or would require more intensive sampling during the period of stream flow, which cannot be justified for intermittent streams. The basis for the need for monthly sampling is not provided in the DEIS.	See the discussion of the basis for sampling frequencies discussion in the rule preamble.
OSM-2010-0021-0047	Society for Mining, Metallurgy &	The definitions used in the Stream Protection Rule need to consider monitoring requirements that reflect relevant	In response to public comment, OSMRE has revised the final rule (Preferred Alternative).

GENERAL			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
	Exploration	regional and permit specific conditions. As defined for Alternative 8 (Preferred), the Stream Protection Rule would require: "monitoring the biological condition of streams using a of a comprehensive, multiassemblage, scientifically defensible bioassessment protocols to document the biological condition of all perennial and intermittent streams and a representative number of ephemeral streams within the proposed permit and adjacent areas over multiple seasons (at a minimum spring, summer, and fall)." This general monitoring requirement does not recognize the biological and ecological variation in ephemeral streams across the seven coal regions defined by OSMRE for promulgation of the Stream Protection Rule. The monitoring requirement to prepare a scientifically defensible bioassessment of a representative sample of ephemeral streams for all areas does not appear to reflect the variation of the ecology and hydrology of ephemeral streams in the s even coal mining regions. The information used to prepare a scientifically defensible bioassessment should reflect conditions that are applicable to the area (Levick, Fonseca and Goodrich, 2006); (Hart, Kirk and Maggard, 2011).	Per 816.37, biological monitoring is required only for perennial and intermittent streams.
OSM-2010-0021-0049	Interstate Mining Compact Commission	Alternative 2 (also 3, 4, 5, 6, and 8 (Preferred))--Continuous on-site rainfall measurement requirements; OSMRE should not require continuous on-site rainfall measurement because it is unnecessary and in excess of what is required in the NPDES program. For decades industry has utilized continuous rainfall measurements from the closest available rainfall gauge. This practice is scientifically valid if the rain gauge is geographically close and climate characteristics do not vary between the gauge and the site.	In response to public comments we have added final paragraph 780.23(b)(1)(ii)(C) to allow, at the discretion of the regulatory authority, a single self-recording device to provide precipitation monitoring data for multiple permits that are contiguous or nearly contiguous provided the device can provide adequate and accurate coverage of precipitation events occurring in that area.
OSM-2010-0021-0049	Interstate Mining Compact Commission	Biological Monitoring Section 2.5.2.1, p. 2-44, second bullet Alternative 2 (also 3, 4, 5, 6, and 8 (Preferred)) --Annual monitoring of biological condition required; Annual monitoring of biological communities does not provide the necessary information to determine what is happening to the community based on mining. Many other variables contribute to biological community changes (i.e. drought, floods, water temperature), and it would be difficult if not impossible to identify the specific causes.	The information obtained from the biological condition monitoring plan should be evaluated alongside the other parts of the water monitoring requirements, such as the surface-water and groundwater monitoring requirements of the alternatives. Taken together, the once-a-year biological condition monitoring and the other more frequent monitoring requirements for surface and groundwater, will allow the regulatory authority

GENERAL			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
			to have the data necessary to identify trends that indicate that an operation is at risk of causing material damage to the hydrologic balance outside the permit area.
OSM-2010-0021-0049	Interstate Mining Compact Commission	Alternative 2 (also 3, 4, 5, 6, and 8 (Preferred))-- "Quarterly monitoring until final bond release (assuming no adverse trends in data which would lead to material damage to the hydrologic balance requirement) consisting of the same suite of analytes sampled for during baseline data collection;"Sampling for over 25 constituents on a quarterly basis for years will be difficult to analyze and use, and represents a significant cost to RAs and industry. OSMRE has not established any thresholds, limits, or corrective action plans. OSMRE has not considered the unique characteristics of each coal producing region or economic costs in developing these water quality monitoring alternatives.	OSMRE disagrees with this comment. In crafting the alternatives, including the Preferred Alternative, OSMRE has contemplated regulatory revisions that would provide minimum nationwide standards while also providing each regulatory authority with the flexibility to tailor requirements, such as in defining material damage to the hydrologic balance outside the permit area and defining evaluation thresholds, to meet the needs of its jurisdiction while ensuring minimal standards are met.
OSM-2010-0021-0049	Interstate Mining Compact Commission	Alternative 1 (No Action Alternative) (Regulatory Authority- PHC) Chapter 4, p. 4-48 "However, there are shortcomings in the current regulations implementing SMCRA. Insufficient baseline data can make it difficult or impossible for the regulatory authority to determine whether problems detected during and after mining are a result of the mining operation or are instead related to other sources. Although the regulations require baseline characterization they do not establish standard protocols for determining the placement and number of water sampling points." OSMRE presumes there are "shortcomings" in the baseline data, but provides no substantiation in this assertion. These perceived shortcomings do not exist in many states, and OSMRE fails to provide specific examples. For example, in Kentucky the KPDES program requires substantial monitoring programs within mining permits.	No change is necessary in response to this comment. The assertion that one state has "substantial" monitoring does not address the need for nationwide standards to ensure adequate premining data at all sites of proposed mining to establish a comprehensive baseline that will facilitate evaluation of the effects of mining. As explained in the text of the EIS, the existing rules require data only for a limited number of water-quality parameters rather than the full suite needed to establish a complete baseline against which the impacts of mining can be compared. The existing rules also contain no requirement for determining the biological condition of streams within the proposed permit and adjacent areas, so there is no assurance that the permit application will include baseline data on aquatic life.
OSM-2010-0021-0070	Luminant Mining Company LLC	Contrary to the unsupported conclusions of the DEIS, Luminant expects significant costs resulting from permitting. We project a substantial (multi-million dollar) increase in one-time environmental baseline costs as a result of additional studies of groundwater, surface water, land use, wildlife, and biological condition, as well as other mine permitting costs resulting from greater scope of jurisdiction and data collection. A significant portion of	The SPR is likely to result in costs to operators, which include additional administrative time spent on baseline data collection, monitoring, permitting applications and other compliance-related activities. These costs have been revised and increased in the Final RIA. Details regarding specific costs for each permit are described in the PRA analysis in the preamble to

GENERAL			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		these costs are associated with assessing characteristics of properties that Luminant has no access to—such as the requirement to collect data on historical uses of lands adjacent to mining sites that are owned by third parties.	the final rule and are summarized in Chapter 4 of the RIA. These costs are part of the costs presented in Section 4.1 of the EIS.
OSM-2010-0021-0060	Ohio Department of Natural Resources	The amount of baseline data required to be collected in the proposed rule appears, in some cases, to be excessive. We can, in many cases, adequately determine baseline conditions using focused, representative and strategic sampling points and make defensible inferences on baseline conditions that would apply to the site.	The final version of the rule, i.e. the Preferred Alternative, clarifies that the regulatory authority should identify local "parameters of concern," if applicable, and include them in the required baseline monitoring data.
OSM-2010-0021-0060	Ohio Department of Natural Resources	"Rule elements related to monitoring and the definition of material damage to the hydrologic balance may improve water quality at surface mine sites, as would changes in mine site practices related to stream restoration and fills." These statements are very subjective in nature and may or may not even be accurate.	OSMRE's explanation for these statements is provided in Table 4.2.1-1. The referenced text has been clarified and a specific reference to this exhibit has been added.
NA	FWS	We recommend that OSMRE and RAs identify when a mining proposal may result in a series of, or "incremental" permits at the beginning of the permit process. A review of the maximum extent of a proposal at the beginning of the permit process will help to identify any potential changes to the mine plan and associated waste management plan. Any changes to the mining plan or waste handling facilities or techniques such as slurry pits using water as a final overburden cover of the slurry bed need to be identified at the beginning of the process.	See responses provided in the preamble for comments related to 30 CFR 783.26 and 784.40.
OSM-2010-0021-0696	Murray Energy Corporation	Various non-mining factors can play a key role in the rate and ultimate level of stream recovery. These include the nature and variability of the local geology and soils, immediate watershed land uses such as agriculture, annual rainfall variability, natural variability in biological communities in a given watershed or stream, invasive species, or year-to-year variability in rainfall. Such factors should be considered on a site-specific basis, and a prescriptive monitoring requirement is therefore not necessary and could detract from more focused and beneficial monitoring efforts. The goal of baseline monitoring should be to provide data that is useful in setting reclamation goals and identifying factors influencing site-specific biological communities.	OSMRE agrees that the factors listed in the comment are important to the site-specific characterization of an operation and the establishment of the reclamation plan. The listed factors are, without exception, addressed in requirements of the rule for site specific data. For example, the baseline data requirements contained in 30 CFR 780/784.19 requires information on hydrology, geology and aquatic biology to determine the nature and extent of the hydrologic reclamation plan and monitoring plans. The requirements recognize invasive species challenges as well; the applicant must describe measures that will be taken to avoid invasive species establishment on reclaimed areas or to control those species if

GENERAL			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
			they do becom eestabalished. 30 CFR 780/784.12.
OSM-2010-0021-0696	Murray Energy Corporation	Existing regulations require sufficient data to fully characterize the baseline conditions at a prospective mine. As outlined in the DEIS No Action Alternative, the current baseline data collection requirements include developing data related to the quantity and quality of groundwater and surface water, as well as detailed characterization of site geology as it relates to reclamation goals.... Additional data collection has no evident benefit, would be a waste of time and resources that could be better allocated, and has not been justified by a specific need or reclamation goal.	OSMRE disagrees and has made no changes to the alternatives considered in response to this comment. Expanded baseline data requirements would be determined by the regulatory authority. The regulatory authority is in the best position to identify those local parameters of concern, if applicable, and include them in the required baseline monitoring data. Any parameters of concern the regulatory authority identifies will more accurately reflect the constituents that could potentially impact water resources during coal mining and reclamation activities in their specific region of the country. We anticipate that, during the development of the permit application package, the applicant will take part in this process by consulting with the regulatory authority about which, if any, additional parameters should be added to the baseline monitoring plans.
OSM-2010-0021-0696	Murray Energy Corporation	Finally, the assumptions stated in OSMRE's DEIS, that mines per se are degrading streams and affecting aquatic life is unmerited by OSMRE's Annual Reviews of mining activity in coalmining regions (see http://www.osmrc.gov/programs/oversight.shtm).	OSMRE inspections and other oversight activities in primacy states, including the annual evaluation reports, focus on the success of state regulatory authorities in achieving compliance with the approved regulatory program for the state.Directive REG-8, which establishes policy and procedures for the evaluation of state regulatory programs, specifies that the offsite impacts identified in annual evaluation reports do not include impacts from mining and reclamation that are not regulated or controlled by the state program. The evaluation reports include only those offsite impacts of coal mining operations that would constitute a violation of the approved regulatory program. Offsite impacts that would not be a violation of the approved program are not identified. In other words, the annual evaluation reports generally do not identify or discuss situations in which the existing regulations provide inadequate

GENERAL			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
			protection. Directive REG-8 provides discretionary authority for evaluations of impacts that are not prohibited by the regulatory program, but that authority may be exercised only if both we and the state agree to do so and if they are not characterized as offsite impacts. Historically, that discretionary authority has not been exercised.
OSM-2010-0021-0696	Murray Energy Corporation	Alternative 8 (Preferred Alternative) Section ES.5, p. ES-17, second paragraph "Sampling, analysis, and biological assessment methods would follow recognized protocols . . . ." This statement is unclear at best. States have a myriad of protocols for biological assessments that vary based on the purpose of those assessments (e.g., support of NPDES permit or 303(d) listing criteria).... At a minimum, OSMRE must specify what "recognized protocols" it intends to apply in order to provide a meaningful opportunity for notice and comment.	In responding to comments on the proposed rule OSMRE has conducted thorough research on the matter of the availability and use of biological assessment protocols. Several arid and semi-arid states across the United States have multimetric bioassessment protocols for perennial streams and/or intermittent streams that have been established by Clean Water Act authorities.[18] In their comments on the proposed rule, several SMCRA regulatory authorities in the western states provided evidence of rigorous protocols for determining the biological condition of perennial streams that are already in place. Also, the U.S. EPA has provided further evidence for the establishment of sampling protocols and indices in wadeable, perennial streams.[19] The ability to obtain information through multimetric bioassessment protocols is currently available on national, regional, and permit-specific levels and the ability to establish effective baseline information on all perennial streams, no matter

			the size, habitat type, or vegetative cover is attainable using the best technology currently available.
OSM-2010-0021-0696	Murray Energy Corporation	Section 2.4.1.1, p. 2-5 This section implies that the existing baseline data collection requirements are not adequate. However, in many states (e.g., MT, WY) substantially more information is required than the minimum described here.	No change is necessary in response to this comment. Section 2.4.1.1 merely describes the existing federal requirements within the 30 CFR 780.21 and 780.22.
OSM-2010-0021-0696	Murray Energy Corporation	Results of Quantitative Analysis of Surface Water Impacts Section 4.2.1.4, p. 4-75, first paragraph Once again, OSMRE suggests that more monitoring will result in better water quality because issues can be resolved quickly, despite the fact that its effectiveness depends largely on state permitting and enforcement resources. There is little room to change mining plans because coal reserves are stationary.	No change is necessary in response to this comment. Monitoring can lead to the resolution of problems without changes to mining plans. Additionally, monitoring will provide the regulatory authority with the information it needs to more readily address water quality issues. The commenter is correct that the effectiveness of a regulatory authority's program depends, in part, on permitting and enforcement resources. However, this limitation does not negate the need for monitoring or affect the fact that effective monitoring will lead to better water quality.
OSM-2010-0021-0696	Murray Energy Corporation	Effects of the Current Regulatory Environment (the No Action Alternative)Section 4.2.1.1, p. 4-49, first paragraph, OSMRE assumes that no sites are being monitored. In Kentucky, the KPDES programs already establish and monitor baseline conditions.	The Clean Water Act is not as comprehensive as SMCRA with respect to protection of the hydrologic balance. The Clean Water Act does not require establishment of a premining baseline and it only requires monitoring of point-source discharges. SMCRA requires that permit applications include baseline information so that the potential impacts of mining can be assessed at the time of permit application and so that impacts that occur during mining and reclamation can be readily identified and evaluated. SMCRA also requires monitoring of both the quality and quantity of surface water and groundwater, as well as monitoring sites located above and below the mine site. Therefore, deferral to state Clean Water Act authorities would not achieve the same results as the stream protection rule.
OSM-2010-0021-0696	Murray Energy Corporation	Effects of the Current Regulatory Environment (the No Action Alternative) Section 4.2.1.1, p. 4-49, first paragraph, last two sentences	Thank you for the comment. We have deleted this text because the data set that it refers to cannot be verified as complete or up to date;

GENERAL			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		OSMRE should also clarify whether the NOIs it has received are related to surface or underground mining.	OSMRE does not require the state SMCRA regulatory authorities to report all NOIs received.
OSM-2010-0021-0696	Murray Energy Corporation	Action Alternatives and Potential Effects on Water Resources Section 4.2.1, p. 4-55, Table 4.2.1-1, "Baseline Data Collection and Analysis" row "Additional baseline characterization of surface water and groundwater provide a better understanding of the premining hydrologic regime..." The proposed increased monitoring would have little effect in some western jurisdictions, such as Montana, where this level of baseline data collection is already substantially realized (see Mont. Admin. R. 17.24.304).	Benefits were determined through the model mine analysis, which used actual permit data from current mines to design and analyze thirteen "representative" model mining operations, which are categorized by region and size (tons of coal produced annually). The model mines represent actual operations that have been permitted and implemented under existing regulations at the state and federal level and therefore already take into account existing protections and benefits of existing regulations in the manner in which they are actually applied.
OSM-2010-0021-0696	Murray Energy Corporation	Action Alternatives and Potential Effects on Water Resources Section 4.2.1.2, p. 4-55, Table 4.2.1-1, "Monitoring During Mining and Reclamation" OSMRE fails to explain how often the data are going to be reviewed by the regulatory authority. Because there is no corrective action plan, OSMRE should clarify how the mine operator should plan for changes to its operations and how approvals would be secured should they be needed.	These procedures are specifically discussed in existing regulations and also in the preamble for the final rule in the discussion of evaluation thresholds.
OSM-2010-0021-0696	Murray Energy Corporation	OSMRE expects to improve water quality by increasing water monitoring of each permit issued. Again, OSMRE is stating this as if no monitoring is currently occurring; however, monitoring is occurring.	Thank you for the comment. OSMRE acknowledges that monitoring currently occurs under both the Clean Water Act and SMCRA. The Clean Water Act is not as comprehensive as SMCRA with respect to protection of the hydrologic balance. The Clean Water Act does not require establishment of a premining baseline and it only requires monitoring of point-source discharges. SMCRA requires that permit applications include baseline information so that the potential impacts of mining can be assessed at the time of permit application and so that impacts that occur during mining and reclamation can be readily identified and evaluated. SMCRA also requires monitoring of both the quality and quantity of surface water and groundwater, as well as monitoring sites

GENERAL			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
			located above and below the mine site. Therefore, deferral to state Clean Water Act authorities would not achieve the same results as the stream protection rule. Furthermore, monitoring under the existing regulations of SMCRA is not sufficient; studies (summarized in the rule, DEIS and RIA) find that negative effects of mining continue, in particular, elevated levels of arsenic, selenium, iron, aluminum, sulfate, and manganese, as well as increased acidity and elevated conductivity in downstream waters, and demonstrate the need for additional regulation focused on reducing these impairments.
OSM-2010-0021-0068	Earthjustice	OSMRE proposes to require restoration of stream form only for ephemeral streams, not restoration of ecological functions. DEIS at ES-21, ES-23, ES-30, 4-97 to 4-98. OSMRE also proposes to limit the definition of the scope of material damage to perennial and intermittent streams. 80 Fed. Reg. at 44,588 (§ 701.5). However, as OSMRE recognizes, ephemeral streams serve important functions in watersheds, such as production and transport of food resources [....] Fifty nine percent of the streams in the U.S. are ephemeral or intermittent. DEIS, p. 3-134. OSMRE provides no scientific reason for not restoring their functions. Failure to do so would mean that ephemeral streams could obtain failing scores on stream condition indices and be listed as impaired on § 303(d) lists due to mining activities, without any requirement that they be restored to pre-mining functional conditions.	Please see the discussion of this issue in the preamble to the final rule, specifically in Section IV.M. "*Should Ephemeral Streams Receive the Same Protections as Intermittent and Perennial Streams?".*
NA	EPA	Ideally, consideration of the appropriate mining alternative and the potential cumulative effects associated with that alternative would be considered at a site-specific or watershed scale based on existing background conditions.	We agree that analysis at the mine level is important to understand. However, due to the broad geographic scope and timeframe for the analysis, we are unable to forecast conditions at every future mine site as part of this national-scale EIS. The 13 model mines across the seven major coal regions were developed in order to capture regional variability in terms of mining methods as well as regional context as much as was feasible.
OSM-2010-0021-0696	Murray Energy Corporation	Section 2.4.9.2, p. 2-41, fourth paragraph OSMRE does not consider cost in the discussion of	The RIA for the EIS provides a quantitative evaluation of the costs and benefits of the rule

		alternative methods for avoiding placement of excess spoil or coal mine waste in or within 100 feet of streams. The absence of cost consideration in the alternatives evaluation is not consistent with federal guidance on consideration of alternatives and options in federal decision-making.	alternatives, in compliance with Federal requirements. NEPA does not require a formal cost evaluation.

2. Alternatives

ALTERNATIVES			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
OSM-2010-0021-0066	NMA	Alternative 8 (Preferred) would redefine "perennial stream" in a manner that is substantively identical to the USACE's definition of that term in Part F of the 2012 reissuance of the nationwide permits under section 404 of the CWA. See 77 FR 10184, 10288 (Feb. 21, 2012). The DEIS does not explicitly state that definition contained in the cited document. The definition of perennial streams per the cited text is as follows: "[a] perennial stream has flowing water year-round during a typical year. The water table is located above the stream bed for most of the year. Groundwater is the primary source of water for stream flow. Runoff from rainfall is a supplemental source of water for stream flow." The DEIS should state the definition provided in the cited text directly rather than referencing a document produced by another agency and subject to future changes; the definition also is scientifically unsupportable.	No change has been made in response to this comment. The point of referring to the reader to the Feb. 21, 2012 CWA definition is specifically to define these waters per that notice. Future changes to the definition would not change the definition as conveyed specifically in the Feb. 21, 2012 notice.
OSM-2010-0021-0066	NMA	The definition of stream types for Alternative 8 provided in the DEIS (Section 2, Description of Alternatives) does not provide a definition for intermittent and ephemeral streams. Since the allowable actions in and around streams mention intermittent and ephemeral streams, the definition for intermittent and ephemeral streams also needs to be provided.	Please refer to section 701.5 of the final rule (Preferred Alternative). Definitions for both intermittent and ephemeral streams are provided there.
OSM-2010-0021-0048	North American Coal	Finally, we find that the projected impacts under the proposed Alternative 8 (Preferred Alternative) are massively incorrect. Possibly the best way to correct these errors is for OSMRE to review and consider the comments submitted under the closely related docket for the Stream Protection Rule, OSM-2010-0018.	We have reviewed all comments in all SPR dockets. The commenter's assumptions about the rule interpretation differ from OSMRE's. These differences lead to different assumptions about the impacts of the rule. Please refer to the final rule preamble for responses to comments submitted to the rule docket.
OSM-2010-0021-0059	CONSOL Energy	The DEIS does not consider enough alternative technology options for protecting streams to be considered complete. There are many other technologies and best management-practices currently in use by the coal mining industry that could have been included in the EIS.	The analysis conducted in the EIS is conducted on the impacts resulting from operations under the existing regulations in comparison to impacts that would occur under the various scenarios of regulation captured in the alternatives. The model mine analysis reviewed current mining permit data to

ALTERNATIVES			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
			generate typical mines, model mines, for each region. Therefore to the extent that these technologies and practices are in current use they have been incorporated in the analysis.
OSM-2010-0021-0060	Ohio Department of Natural Resources	Chapter 4, Page 4-49, Impacts of the No Action Alterative on Water Resources: Surface Water and Groundwater Effects"Both surface and underground mining operations have the potential to adversely affect surface water quality .... The effects are generally more pronounced in areas with a long history of mining, such as sites disturbed prior to the enactment of SMCRA in 1977, as compared to more current operations, as mining practices have improved over time. However, as described in the studies presented below, mining under current regulations is continuing to result in physical and chemical effects on surface waters." Given the improvements cited, it would seem reasonable to address any current concerns through enforcement and oversight rather than placing all coal mine operators in one box. The EIS recognizes that pre-SMCRA sites have remaining and sometimes long-term impacts to land and water resources but those impacts will not be mitigated through the proposed stream protection rule, with the exception of advancing remining permits.	No changes were made as a result of this comment. It is common practice for remining operations to repair the damage caused by pre-law mine operations. While SMCRA does not limit operations to only remining operations, and does not require operators to reclaim abandoned mine land features outside of a permit disturbance boundary, any previously mined areas that are re-disturbed during the course of remining must be reclaimed according to all of the requirements of SMCRA. The implementing regulations for SMCRA already contain mechanisms to provide for enforcement of existing regulations including those that provide the regulatory authority the ability to cite an operator for violation of permit conditions, including violation of permit conditions driven by CWA and ESA requirements. The implementing regulations of SMCRA also contain mechanisms for OSMRE to assess state SMCRA program compliance with the federal regulations and to require corrections of deficiencies where they exist or to alternatively bring the program for that state back under direct federal control. These existing mechanisms do not completely address all concerns as expressed in the purpose and need for the rule.
OSM-2010-0021-0696	Murray Energy Corporation	The DEIS also fails to adequately examine alternatives. Specifically, OSMRE did not examine an alternative under which, regardless of whether and how the agency further regulates mountaintop mining and associated concerns, it would not adopt new regulations for underground mine subsidence. Yet, for most of the history of the development of the rule, OSMRE did not consider further subsidence regulation. It is nonsensical that the DEIS does not even consider the alternative that OSMRE long thought it would undertake-further regulation of mountaintop mining but no	The proposed rule merely clarified the already existing obligation to prevent material damage to the hydrologic balance outside the permit area applied to areas overlying the underground workings of an underground mine, which is part of the adjacent area as that term is defined in section 701.5 of our regulations. As explained in more detail in the definitions section of the preamble to the final rule we have always considered the definition of "material damage

ALTERNATIVES			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		further regulation of subsidence from underground mining.	to the hydrologic balance outside the permit area" to include the area overlying the underground workings of an underground mine as part of the evaluation area for prevention of material damage to the hydrologic balance outside the permit area. Although this has been our longstanding position and is clearly mandated by SMCRA, the definition of material damage to the hydrologic balance outside the permit area that we are finalizing today removes any of the ambiguity that may have resulted in this comment.
OSM-2010-0021-0696	Murray Energy Corporation	OSMRE's DEIS fails to adequately examine alternatives for the Proposed SPR. Most importantly, OSMRE did not examine an alternative under which it would adopt new regulations for mountaintop mining and associated concerns but would not adopt new regulations addressing underground mine subsidence. This is particularly shocking since for most of the development of the rule, OSMRE did not indicate it was considering further subsidence regulation. The DEIS also fails to evaluate a sufficient range of alternatives addressing other aspects of the Proposed SPR. OSMRE's failure to evaluate a reasonable range of alternatives renders its EIS process inadequate.	Please see the Master Response on Alternatives regarding the range of alternatives considered and the response to the preceding comment regarding subsidence.
OSM-2010-0021-0696	Murray Energy Corporation	Additionally, none of the action alternatives contains any differences in sampling frequency, location, parameters or biological communities sampled, or the duration of sampling. It does not appear that OSMRE considered a reasonable range of alternatives for these elements, especially considering the variation in costs and potential permit delays associated with increased sampling and data collection and the potential regulatory involvement in reviewing and conducting inspections relating to this data. Furthermore, the alternatives analyzed for the definition of "material damage to the hydrologic balance outside the permit area" and evaluation thresholds do not encompass a reasonable range of alternatives as defined by NEPA. Despite identifying four potential alternatives for a material damage definition and three alternatives for a evaluation threshold in the NOI (in addition to the No Action Alternative) the only alternatives for this element considered were the No Action Alternative and Alternative	Thank you for your comment. Please refer to the Master Response on Alternatives for a discussion of the structuring of the alternatives related to the rule elements.

ALTERNATIVES			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		2, the most protective. OSMRE failed to consider other more moderate alternatives for these elements. Because this is the first time material damage will be defined on the federal level and the first time evaluation thresholds have been proposed, OSMRE should have considered a wider range of alternatives given the potential impact this definition will have on the regulatory authority and the regulated community. As a result of these, among other, omissions, the DEIS fails to analyze a reasonable range of alternatives and does not meet the requirements of NEPA.	
OSM-2010-0021-0066	NMA	The alternatives in the DEIS do not adequately capture the range of potential alternatives that could be equally effective at protecting stream resources with less impact on the industry.	Thank you for your comment. Please refer to the Master Response on Alternatives fpr a discussion that addresses this and other similar comments on the range of alternatives considered.
OSM-2010-0021-0066	NMA	The DEIS ignores regional ecological differences and how those differences affect implementation of the rules and/or the adequacy or need for the SPR. In particular, the DEIS alternatives appear to reflect a one-size-fits-all approach to surface and underground mining practices throughout the US.	No change to the EIS is necessary in response to this comment. OSMRE has addressed similar comments throughout the preamble to the final rule, and ensured that flexibility exists where needed to accommodate regional characteristics within the nationwide framework of the rule. For example Section section 780.28 and 816.56 incorporate site specific requirements and demonstrations when mining is planned in or near an intermittent or perennial stream, allowing for differences in topography, geology, and climate in the various regions of the country. For further discussion of flexibility provided to accommodate site specific characteristics see Section IV. C. "We Have Not Accorded Sufficient Deference to Principles of Cooperative Federalism and the Primacy of States with Approved Regulatory Programs." within the preamble to the final rule.
OSM-2010-0021-0066	NMA	The DEIS does not include the most practical alternative, which is the enforcement of existing federal and state regulations related to mining across the different regions. The existing regulations, if enforced, would meet the stated purpose and need of the action and include the more important social, economic and energy security needs not addressed.	Please refer to Master Response on Alternatives for a discussion of an alternative based on existing regulations.

ALTERNATIVES			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
OSM-2010-0021-0066	NMA	The DEIS alternatives were nearly all the same and did not include a range of alternatives so that important issues such as social and economic alternatives could be evaluated.	Please refer to Master Response on Alternatives for a discussion of the range of alternatives considered.
OSM-2010-0021-0066	NMA	Table 2 was prepared to allow a better comparison of the features distinguishing (or failing to distinguish) the elements of the nine alternatives considered by OSMRE in its DEIS. Experts reviewed OSM's description of each alternative as articulated by OSMRE in the DEIS, particularly sections ES.4, ES.5, ES.6, 2.4, and 2.5, and compiled the table based on the information contained in those sections. Comparing the alternatives element by element, it is evident that the alternatives are in many cases duplicative, do not include alternatives contemplated by the NOI, and fail to consider a reasonable range of options as required by NEPA.	Please refer to Master Response on Alternatives for a discussion of the range of alternatives considered.
OSM-2010-0021-0066	NMA	While the No Action Alternative and Alternative 2 are vastly different in terms of the parameters required to be sampled, the remaining alternatives are some small variation or identical to Alternative 1 or 2. Not only is there no moderate alternative, the range of alternatives does not consider a reasonable range of options relating to frequency of sampling, location of sampling, timing of sampling, etc. This is in direct contrast to the NOI, which contemplated alternatives related to frequency, location, duration, as well as what biological, chemical, physical, and hydrological parameters to be sampled. The alternatives considered for baseline data collection for groundwater and geology and the alternatives considered for monitoring during mining similarly do not consider a reasonable range of alternatives, especially when compared to the alternatives contemplated by the NOI.	As the lead agency OSMRE is ultimately responsible for determining the scope and content of the environmental impact statement. The NOI is published very early in the process, even before the scoping process is conducted, in compliance with 40 CFR 1501.7. The scoping process provides, among other things, the opportunity for participants to identify concerns, potential impacts and relevant effects of past actions and possible alternative actions. Scoping is therefore done very early in the process before the analysis or deliberations of the results have occurred; it is therefore a natural and expected outcome of the NEPA process that the Preferred Alternative and alternatives would change between the earl identification provided at scoping. The input received during scoping efforts is important to help define the issues for consideration; however suggestions obtained during scoping are not binding but are only important options for the lead agency to consider (43 CFR 46.235(b)).
OSM-2010-0021-0066	NMA	Similarly, the element defining "material damage to the hydrologic balance outside the permit area" contains only two options: No Action of Alternative 2. The NOI specifically mentioned four different alternatives for this element, yet	As the lead agency OSMRE is ultimately responsible for determining the scope and content of the environmental impact statement. The NOI is published very early in the process,

		only one alternative other than the No Action alternative (no definition) is addressed.	even before the scoping process is conducted, in compliance with 40 CFR 1501.7. The scoping process provides, among other things, the opportunity for participants to identify concerns, potential impacts and relevant effects of past actions and possible alternative actions. Scoping is therefore done very early in the process before the analysis or deliberations of the results have occurred; it is therefore a natural and expected outcome of the NEPA process that the Proposed Action and alternatives would change between the earl identification provided at scoping. The input received during scoping efforts is important to help define the issues for consideration; however suggestions obtained during scoping are not binding but are only important options for the lead agency to consider. 43 CFR 46.235(b).
OSM-2010-0021-0066	NMA	In some cases, OSMRE proposed alternatives for elements that would be impossible to implement, which results in additional failures to consider a reasonable range of alternatives. For example, for the AOC variances element, Alternative 2 would prohibit all mountaintop removal operations or all variances. Since SMCRA specifically authorizes an AOC variance for mountaintop removal and steep slope mining, OSMRE cannot eliminate mountaintop removal or steep slope operations without an amendment to SMCRA. Since OSMRE acknowledges that prohibiting mountaintop removal operations or other variances “may” require an amendment to SMCRA, we are left with only two alternatives under consideration for the element of AOC variances – the No Action Alternative, or the Preferred Alternative.	Please refer to Master Response on Alternatives for a discussion of what constitutes a reasonable alternative under NEPA.
OSM-2010-0021-0066	NMA	Similarly to some of the other elements discussed above, the revegetation, topsoil management, and reforestation components do not provide a reasonable range of alternatives sufficient to consider in the DEIS. For each component, only the No Action Alternative and the Preferred Alternative are considered as options. The Preferred Alternative analyzed by OSMRE seems to be more stringent than the other alternatives OSMRE stated that it	Please refer to Master Response on Alternatives, specifically the discussion of rule elements and structuring of the alternatives.

ALTERNATIVES			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		was initially considering. Thus, OSMRE has the choice of the No Action alternative or the most stringent Preferred Alternative, with no moderate or less stringent options.	
OSM-2010-0021-0066	NMA	Other alternatives that should have been considered include progressive mining through streams with progressive restoration, and allowances for changes in hydrology, approximate original contour, and other physical conditions. The alternatives would provide for beneficial uses (as defined under the CWA) that occur premining and are attained postmining (with exceptions in areas where other land uses have affected the attainment of those uses)	The comment did not provide sufficient detail to understand what specific additional flexibilities the commentor would like to see included in the alternatives, as the suggested items are already encompassed in existing law and regulation. For example, our existing regulations (see 30 CFR 816/817.100) require that reclamation efforts occur as contemporaneously as possible with the mining operations; therefore progressive mining with progressive restoration is already a requirement analyzed as part of the no action alternative. The alternatives considered already do allow for changes in hydrology, just not to the extent that these changes would cause material damage to the hydrologic balance outside the permit area. Assessment of the probable cumulative impact of all anticipated mining in the area on the hydrologic balance to ensure that the proposed operation has been designed to prevent material damage to the hydrologic balance outside the permit area is a requirement of SMCRA itself, and is indicative of the understanding that some degree of hydrologic change can and would occur that would not necessarily be a violation of the Act. Section 510(b)(3). Allowances for deviation of the approximate original contour are similarly already provided in existing regulations that implement the exception to original contour restoration requirements found in Section 515(c) of SMCRA.
OSM-2010-0021-0066	NMA	The DEIS indicates that: Alternative 4 defines perennial, intermittent, and ephemeral streams in terms of flow regime, channel and substrate characteristics, and the biological community, if any, found in the stream. The definition of an intermittent stream would no longer include the one-square-mile watershed criterion. The flow regime, channel and substrate characteristics, and the biological	Clarification on how these streams would be defined under Alternative 4 has been added to the detailed description of this alternative within chapter 2.

ALTERNATIVES			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		community are not defined. As such, it is impossible to determine which category a particular stream falls into. Therefore, it is impossible to determine which portion of the SPR would apply to any particular water feature. This definition is wholly inadequate.	
OSM-2010-0021-0048	North American Coal	OSMRE also fails to account for their findings, or lack of findings, in state oversight reports conducted over the past five years since this process began. The agency says that "despite the enactment of SMCRA and the promulgation of federal regulations implementing the statute, surface coal mining operations continue to have negative effects on streams, fish and wildlife. These conditions are documented in the literature surveys and studies…"6 However, OSMRE has the duty to assure compliance with the Act, and does this through rigorous state oversight. Documentation of this process is found in annual oversight reports. We find it curious and disconcerting that OSMRE completely fails to emphasize, or even reference, actual evaluations of impacts, conducted by their own agency on an annual basis in all coal mining states, but instead relies on other "literature surveys and studies…"Contrary to OSM's assertion in the DEIS, there are actually very few "negative effects", as documented in OSM's own oversight reports. As these OSMRE state oversight reports directly address and specifically describe "current regulatory requirements, policies, and practices under SMCRA, the Clean Water Act, and other federal and state laws…" [emphasis added] under Alternative 1 (No Action Alternative)7 it's extremely important that OSMRE consider these as best sources of information to accurately describe potential effects under the No Action Alternative. OSMRE must discuss this important information in a detailed and comprehensive manner, as it encompasses the official record of state primacy performance under the Act and its existing implementing regulations. Failure to account for this makes the DEIS incomplete, and consequently frustrates the agency's ability to truly take a "hard look" at the proposed rule compared to current (i.e., "No Action Alternative") conditions that OSMRE documents annually.	OSMRE inspections and other oversight activities in primacy states, including the annual evaluation reports, focus on the success of state regulatory authorities in achieving compliance with the approved regulatory program for the state. Directive REG-8, which establishes policy and procedures for the evaluation of state regulatory programs, specifies that the offsite impacts identified in annual evaluation reports do not include impacts from mining and reclamation that are not regulated or controlled by the state program. In other words, the annual evaluation reports generally do not identify or discuss situations in which the existing regulations provide inadequate protection. While Directive REG-8 provides discretionary authority for evaluations of impacts that are not prohibited by the regulatory program, that authority may be exercised only if both OSMRE and the state agree to do so and if they are not characterized as offsite impacts. Historically, that discretionary authority has not been exercised.
			The findings in the annual evaluation reports do not address the need for the proposed rule because the proposed rule would address

ALTERNATIVES			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
			adverse impacts that historically have been allowed to occur under the existing regulations and which are not captured by the annual evaluation reports. For example, many state programs do not address elevated conductivity and increased selenium levels in streams as a result of mining and reclamation operations. The existing regulations do not specifically mention these parameters, in large part because the adverse impacts on aquatic life were not known when OSMRE adopted the existing hydrology regulations under SMCRA. Accordingly, we do not view the findings in the annual evaluation reports and the explanation of the purpose of the proposed rule in the rule's preamble as contradictory.
OSM-2010-0021-0055	Rocky Mountain Elk Foundation	Our primary concern with the EIS and the preferred Alternative 8 is the emphasis on reforestation. The EIS (ES34) requires "reforestation of previous forested areas and of lands that would revert to forest under conditions of natural succession (a farmland exception exists) in a manner that would enhance recovery of the native forest ecosystem as expeditiously as possible." We contend that in the U.S., which contains eight percent of the world's forests, there are more trees than there were 100 years ago!	We have made no change to the EIS in response to this comment. The emphasis on reforestation in the EIS is consistent with the objective to promote establishing native vegetation. The reestablishment of native species vegetation is of primary importance in reclaiming mined lands, and that the reclamation of these lands can have significant impacts on a stream's watershed and the health of that stream. Benefits to streams from the revegetation of terrestrial lands include the return of the appropriate surface water flow regimes and reestablishment of the proper nutrients and organic matter to the aquatic habitat. Regardless of the postmining land use, the final regulations are sufficiently flexible to allow planting of appropriate plant species specific to the various regions and local habitats, within limitations identified at section 780.12(g).
OSM-2010-0021-0055	Rocky Mountain Elk Foundation	We strongly suggest that OSMRE and its regulators interpret wildlife habitat as an accepted post-mining land use, as it could easily be implemented prior to final bond release and is a much needed element of the ecosystem	No change required to the EIS in response to this comment. Fish and wildlife habitat remains an acceptable post-mining category per the definition of land use at 701.5.
OSM-2010-0021-0056	Utah Mining Association/ NMA	The DEIS fails to provide a range of alternatives that are realistic or support a reasonable purpose and need for the	Please refer to Master Response on NEPA Compliance and the Master Response on

COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		Proposed Action. The alternatives analysis of the DEIS is completely unrealistic and arbitrary. Consequently, the DEIS does not accurately or reasonably portray the environmental, social, or financial impacts of the SPR on the mining industry, local and state economies, or the nation.	Alternatives.
OSM-2010-0021-0059	CONSOL Energy	The DEIS does not take into consideration a comprehensive list of viable alternatives to the element of the proposed SPR. Many of the 16 "regulatory components" that are evaluated by the OSMRE are not reasonable and/or feasible, failing to substantiate a need for the proposed SPR.	OSMRE has received and considered public comment on all components of the proposed SPR. Please see the preamble for the final rule for discussion of these comments and changes we have made as a result.
OSM-2010-0021-0059	CONSOL Energy	The DEIS fails to properly take into consideration the environmental, economic, and safety consideration of the proposed changes and "regulatory components."	The EIS addresses each of these issues. The EIS discusses environmental impacts of each regulatory component in Chapter 4 of the EIS, with section 4.2 specifically focused on natural resource effects. Economic impacts associated with each regulatory component are discussed specifically in Chapter 4.3 of the EIS. Potential impacts to public health and safety are discussed in section 4.3.4 of the EIS.
OSM-2010-0021-0059	CONSOL Energy	The DEIS fails to fully take into consideration the existing robust state regulatory programs and regional differences in topography, ecology, geology, and water chemistry. The existing state programs already meet the stated need for the SPR.	While it is true that the DEIS does not list specific deficiencies or errors in the current state SMCRA regulatory programs this is not indicative of a lack of need for the Proposed Action. OSMRE's annual evaluation reports routinely do not indicate problems with the states' implementation of their programs, however we disagree with the conclusion the commenters attempt to draw from this information, i.e., that our experience does not show that there is a problem that this rule is designed to address. OSMRE inspections and other oversight activities in primacy states, including the annual evaluation reports, focus on the success of state regulatory authorities in achieving compliance with the approved regulatory program for the state. OSMRE Directive REG-8, which establishes policy and procedures for the evaluation of state regulatory programs, specifies that the offsite impacts identified in annual evaluation reports do not include impacts from mining and

ALTERNATIVES			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
			reclamation that are not regulated or controlled by the state program. In other words, the annual evaluation reports generally do not identify or discuss situations in which the existing regulations provide inadequate protection. While Directive REG-8 provides discretionary authority for evaluations of impacts that are not prohibited by the regulatory program, that authority may be exercised only if both OSMRE and the state agree to do so, and if they are not characterized as offsite impacts. Historically, that discretionary authority has not been exercised. Thus, annual reports are of little assistance in assessing how the existing minimum federal standards that are incorporated into the approved state programs could be improved to better implement SMCRA. Part II of the final rule preamble summarizes the water quality and land reclamation problems that developed under the previous rules. In addition, speakers at the public hearings described their experiences with dewatering of streams as a result of subsidence from underground mining operations.
OSM-2010-0021-0068	Earthjustice	OSMRE states in the preamble and DEIS that it considered alternative stream protection requirements that would have provided greater protection to streams, and rejected them because they would interfere with coal production. In making this choice between alternatives, OSMRE has overlooked relevant and important considerations that support adoption of a more protective alternative. Choosing a less protective alternative without fully considering its costs is arbitrary and capricious and violates the National Environmental Policy Act (NEPA).	Thank you for your comment. Please refer to the discussion related to reasonable alternatives within the Master Response on Alternatives.
OSM-2010-0021-0068	Earthjustice	OSMRE states that it rejected more protective alternatives because their alleged negative impact on the nation's energy needs would be too great. 2015 DEIS at ES-36 ("OSMRE determined that the impacts to coal production from this Alternative were so substantial that they ran counter to the mandate under SMCRA 102(f) to balance the need for energy with the protection of the environment.").	The commenter is incorrect that coal production is expected to decline to the extent that OSMRE should have eliminated additional alteratives from consideration, or used this expected decline to justify selection of the most environmentally protective alternative. OSMRE has considered and incorporated

ALTERNATIVES			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		In making this determination, OSMRE failed to consider the fact that the nation's demand for coal is in sharp, sustained decline brought about by structural changes in the way energy markets are functioning.	projected declines in U.S. and global demand for coal in its assessment of the impacts of the alternatives as presented in the EIS and the RIA. As discussed, coal demand is forecast to decline by 15 percent over the time period for analysis. The most environmentally protective alternative (Alternative 2) is anticipated to have a major adverse impact on socioeconomic resources, including employment in the coal sector.
OSM-2010-0021-0054	Kentucky Energy and Environment Cabinet	The Federal Register clearly states that the proposed rule is being based on the 1983 rule language that was in place prior to the 2008 rule, which is the equivalent of the No Action Alternative. However, the statement in the DEIS claims that there is no real difference in impacts between the 1983 rule and the 2008 rule. We find no justification to support this statement, and the statement is actually untrue in most states other than possibly the two that rely on OSMRE for surface mining regulation.	Alternative 9 would require the repromulgation of the currently vacated 2008 Stream Buffer Zone rule. This Alternative would require minimization of excess spoil generation, place limits on excess spoil fill capacity to match the anticipated amount of excess spoil to be generated, and prohibit mining activities in or within 100 feet of an intermittent or perennial stream unless the applicant demonstrates and the regulatory authority finds that avoidance is not reasonably possible. The model mines analysis indicates that the impacts of Alternative 9 would not differ significantly from those of the No Action Alternative because the Clean Water Act requirements and policies discussed in the Regulatory Impact Analysis for this rulemaking and the state AOC and excess spoil policies identified in Section 4.2.3.1 of this DEIS have effectively achieved implementation of this Alternative in Central Appalachia, which is the region in which the 2008 Stream Buffer Zone rule would have had its greatest impact if it had remained in effect. Therefore, if repromulgated, Alternative 9 would now have Negligible effects on socioeconomic resources evaluated in this FEIS.
OSM-2010-0021-0061	Peabody Energy	Peabody urges OSMRE to develop and evaluate regulatory alternatives that address well-documented regional stream issues on a regional basis {i.e., areas for which OSMRE has evidence to support the need to develop new stream protection requirements beyond those in OSM's current rules, with effective enforcement thereof, as augmented by other regulatory changes with respect to streams, as well as	Thank you for your comment. Please refer to the discussion of regional versus nationwide rulemaking alternatives in the Master Response on Alternatives.

ALTERNATIVES			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		changes in mining methods and mitigation related thereto; and areas for which OSMRE can reasonably conclude that its current rules are inadequate to meet SMCRA's command under current regulatory and mining circumstances and reasonable, foreseeable changes thereto). In so doing, Peabody urges OSMRE to work closely with the mining industry to best understand the regional issues with respect to potential impacts to streams from various mining methods and operations, as well as mitigation related thereto.	
OSM-2010-0021-0049	Interstate Mining Compact Commission	OSMRE has failed to develop and evaluate a reasonable range of alternatives. It has failed to consider alternatives that it put forth in the previous NO Is; presented alternatives as "strawmen"; and suggested alternatives that are beyond its rulemaking authority.	Thank you for your comment. Please refer to the discussion of the range of alternatives within the Master Response on Alternatives.
OSM-2010-0021-0049	Interstate Mining Compact Commission	The alternatives are discussed in the context of the eleven principal elements addressed in the regulations. There is no explanation provided by OSMRE for each alternative as to how it was developed and its potential Benefits. There is also no explanation as to why Alternative 8 was chosen as the Preferred Alternative.	Thank you for your comment. Please see EIS Section 2.1 "Development of the Alternatives."
OSM-2010-0021-0049	Interstate Mining Compact Commission	Possible alternatives OSMRE stated that it might consider included the duration of sampling, frequency of sampling, location of sampling, what biological communities are subject to sampling, and what parameters are subject to sampling. OSMRE's analysis of alternatives for baseline data and monitoring are either the No Action Alternative or Alternative 2, with little to no variation between alternatives. The sole variation between Alternative 3 and Alternative 2 for baseline data collection seems to be the difference between discrete or continuous sampling. None of the action alternatives contain any differences in sampling frequency, location, parameters or biological communities sampled, or the duration of sampling. It does not appear that OSMRE considered a reasonable range of alternatives for these elements, especially considering the variation in costs and potential permit delays associated with increased sampling and data collection and the potential regulatory authority involvement in reviewing and conducting inspections relating to this data.	Thank you for your comment. Please refer to the discussion of rule element combinations within the alternatives considered in the Master Response on Alternatives.
OSM-2010-0021-0049	Interstate Mining Compact Commission	Despite identifying four potential alternatives for a material damage definition and three alternatives for a evaluation	As the lead agency OSMRE is ultimately responsible for determining the scope and

ALTERNATIVES			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		threshold in the NOI (in addition to the No Action Alternative), the only alternatives for this element considered were the No Action Alternative and Alternative 2, the most restrictive of mining activities. OSMRE failed to consider other less restrictive alternatives or more moderate alternatives for these elements. Because this is the first time material damage will be defined on the federal level and the first time evaluation thresholds have been proposed, OSMRE should have considered a wider range of alternatives given the potential impact this definition will have on the regulatory authority and the regulated community.	content of the environmental impact statement. The NOI is published very early in the process, even before the scoping process is conducted, in compliance with 40 CFR 1501.7. The scoping process provides, among other things, the opportunity for participants to identify concerns, potential impacts and relevant effects of past actions and possible alternative actions. Scoping is therefore done very early in the process before the analysis or deliberations of the results have occurred; it is therefore a natural and expected outcome of the NEPA process that the Proposed Action and alternatives would change between the earl identification provided at scoping. The input received during scoping efforts is important to help define the issues for consideration; however suggestions obtained during scoping are not binding but are only important options for the lead agency to consider. 43 CFR 46.235(b).
OSM-2010-0021-0049	Interstate Mining Compact Commission	Alternative 2 would effectively prohibit all mountaintop removal operations and all variances. SMCRA specifically authorizes an AOC variance for mountaintop removal and steep slope mining; therefore OSMRE cannot eliminate mountaintop removal or steep slope operations without an amendment to SMCRA. Since OSMRE acknowledges that prohibiting mountaintop removal operations or other variances "may" require an amendment to SMCRA, we are left with only two alternatives under consideration for the element of AOC variances - the No Action Alternative or the Preferred Alternative. In short, OSMRE has failed to analyze a reasonable range of alternatives for the element AOC Variances.	Agencies must consider alternatives even when they are outside their current statutory authority. Please see the Master Response on Alternatives
OSM-2010-0021-0049	Interstate Mining Compact Commission	Another example of this is Alternative 9, where OSMRE considers a scenario in which the 2008 Stream Buffer Zone Rule is promulgated and fully implemented. Engineering analysis of coal industry practices finds that, during the period that the 2008 Stream Buffer Zone rule was in place, the permits issued in Appalachia changed in response to USACE, U.S. EPA, and state policies that are similar to the No Action Alternative. As a result, Alternative 9 is	Thank you for the comment. Please refer to Master Response on Alternatives.

ALTERNATIVES			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		anticipated to have negligible effects on water resources compared to the No Action Alternative	
OSM-2010-0021-0049	Interstate Mining Compact Commission	Alternative 2(Replacement of riparian zone- mining through streams)2.4.2.2, p. 2-15"... reclamation plan must provide for the preservation of a permanent riparian establishment corridor ... at least 100 feet in width ..."This alternative assumes that a riparian zone already exists and can be recreated. In western ephemeral and even intermittent and perennial streams this is often not the case. Where stream flows and climate do not provide enough water, a riparian zone cannot be established. Where streams are incised or in certain soil types, it may be impractical or impossible to have or to recreate a riparian zone of any given width. OSMRE has not considered the diverse environmental conditions of each coal producing region in its analysis.	The requirement for a riparian zone 100 feet in width does not specify that the vegetation within the zone must be water loving. In responding to similar comments on the proposed rule (i.e. the Preferred Alternative or Alternative 8) we have clarified the following: that plantings in streamside vegetative corridors must include appropriate native hydrophytic vegetation, vegetation typical of floodplains, or hydrophilic vegetation characteristic of riparian areas and wetlands to the extent that the corridor contains suitable habitat for those species and the stream and the geomorphology of the area are capable of supporting vegetation of that nature. We also clarified that it was not required to plant hydrophytic or hydrophilic species within those portions of streamside corridors where the stream, soils, or climate are incapable of providing the moisture or other growing conditions needed to support and sustain hydrophytic or hydrophilic species. In these situations, you must plant the corridor with appropriate native species that are consistent with the baseline information concerning natural streamside vegetation included in the permit application, unless otherwise directed by an agency responsible for implementing section 404 of the Clean Water Act, 33 U.S.C. 1344.
OSM-2010-0021-0049	Interstate Mining Compact Commission	Alternative 4 (Restrictions in listed watersheds) 2.4.4, p. 2-23 "Mining operations in watersheds with impaired waters ..." If TMDLs allow trading or other ways of achieving improved conditions, this requirement would potentially override and not allow mining when a net benefit to the impaired stream could result from the mine related activities. OSMRE failed to consider this in its analysis.	Alternative 4 requires additional "enhanced permitting requirements" if a mining operation is proposed in a watershed with impaired waters and the RA expects the proposed coal mining operation would exacerbate the stream impairment. It does not ban coal mining in a watershed with impaired streams, therefore it does not ban operations that would potentially result in a net improvement to water quality.
OSM-2010-0021-0049	Interstate Mining Compact Commission	Alternative 1 (No Action Alternative) (Definitions - Intermittent Stream)	The text is quoting existing regulations which are proposed for change under the SPR.

ALTERNATIVES			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		2.4.1.2, p. 2-7 "An intermittent stream is (1) a stream or reach of a stream that drains a watershed of at least one square mile." This one square mile definition is not accurate in western states where much larger drainage areas may be required to support an intermittent stream.	
OSM-2010-0021-0070	Luminant Mining Company LLC	OSMRE appears to have predetermined that any rule regulating surface mining must be national in scope, given that the DEIS fails even to consider any regionally applicable alternatives, or any approaches focused on those forms of mining that present relevant environmental risks.	Thank you for your comment. Please refer to Master Response on Alternatives. Additionally, please see section IV.D. of the preamble to the final rule.
OSM-2010-0021-0070	Luminant Mining Company LLC	The record demonstrates that OSMRE failed even to consider (never mind analyze) any alternatives with a narrower scope, which are absent from the list of “alternatives and elements considered but dismissed	Thank you for your comment. Please refer to Master Response on Alternatives.
OSM-2010-0021-0070	Luminant Mining Company LLC	OSMRE should have included in its analysis alternatives that had a more limited scope, but that will yield similar Benefits with much lower overall socioeconomic impacts	Thank you for your comment. Please refer to Master Response on Alternatives.
OSM-2010-0021-0070	Luminant Mining Company LLC	In light of the significant socioeconomic impacts and costs of the various alternatives analyzed in the DEIS, but the minimal to non-existent Benefits in certain areas of the country, OSMRE should have considered more narrowly focused alternatives.	Please refer to Master Response on Alternatives.
OSM-2010-0021-0070	Luminant Mining Company LLC	OSMRE has not provided any rational explanation for why a proposed rule intended to address problems in Appalachia instead must apply to all of the nation’s coal-producing regions. A one-size-fits-all approach to surface-mining regulation not only conflicts with SMCRA’s mandate, but also ignores the vast differences between coal-mining regions in the United States. For example, Texas has literally no “mountain-top removal” mining; no “valley fills;” no “steep slope mining;” no underground mining; no remaining abandoned mining lands; no solid rock overburden; no blasting; and no long-term alteration to groundwater composition and quality.	No change to the EIS is necessary in response to this comment. OSMRE has addressed similar comments throughout the preamble to the final rule, and ensured that flexibility exists where needed to accommodate regional characteristics within the nationwide framework of the rule. For example Section section 780.28 and 816.56 incorporate site specific requirements and demonstrations when mining is planned in or near an intermittent or perennial stream, allowing for differences in topography, geology, and climate in the various regions of the country. For further discussion of flexibility provided to accommodate site specific characteristics see Section IV. C. “*We Have Not Accorded Sufficient Deference to Principles of Cooperative Federalism and the Primacy of States with Approved Regulatory Programs.*” within the preamble to the final

ALTERNATIVES			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
			rule.
OSM-2010-0021-0070	Luminant Mining Company LLC	OSMRE states that "[u]nder existing regulations, mining continues to affect downstream water chemistry." (DEIS at 4-50). However, all of the studies cited by OSMRE in support of this proposition were conducted in Appalachia with a focus on surface mining impacts. OSMRE provides no support or evidence for similar impacts in Texas or other non-Appalachia mining regions. Similarly, virtually all of the sources OSMRE relies upon for its assertion that "damage from contaminants released by surface mining persists for decades" relate to conditions in Appalachia. In fact, none of the literature cited by OSMRE supports the nationwide application of a rule to address alleged environmental harms in Appalachia.	OSMRE acknowledges that much of the research on understanding downstream effects of coal mining has been conducted in Appalachia. The history and extent of mining in the Appalachian Basin makes it the subject in the majority of the water quality studies (e.g., Lindberg et al., 2011, Merriam et al., 2011, Petty et al., 2010, Pond et al., 2008, Fulk et al., 2003). In addition, authors have also noted that due to the arid climate and high mineralization of stream water, analyses of this type are more difficult in western regions. Though limited, literature in other regions indicates similar downstream impacts despite obvious difference in geography. To account for these differences, model mines were developed to represent geography, coal production, and other environmental factors of each coal mining region. OSMRE determined that development of a comprehensive, nationally applicable, stream protection rule would be the most appropriate and effective method of achieving the purposes and requirements of SMCRA, as well as meeting the goals set forth in the June 11, 2009, Memorandum of Understanding (MOU) among the U.S. Department of the Army, the U.S. Department of the Interior, and U.S. EPA implementing the interagency action plan on Appalachian surface coal mining. Streams are important components of the hydrologic regime everywhere that streams are found, so there is no scientific reason to limit stream protection efforts to one region of the country. In addition, it is not clear that we have authority under SMCRA to conduct rulemaking on a regional basis.
NA	EPA	Page 4-8, Table 4.0-1: The seven different "Impact Characterization" categories also seem somewhat arbitrary and poorly defined because they rely on vague terminology (e.g., "small/medium/large" area, "short-term/long-term"	OSMRE appreciates U.S. EPA's concern regarding the definitions of the impact characterization categories. We have more clearly defined the geographic scope and duration of the impact for

ALTERNATIVES			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		impact). How are thresholds between categories decided? Given the potential importance of the alternatives comparison, these categories need a quantifiable justification/description.	each resource in section 4.0.3 and in resource-specific sections of chapter 4. The expanded definitions better articulate how impacts were determined for each resource in the FEIS.
OSM-2010-0021-0696	Murray Energy Corporation	The DEIS seems to make the case that the federal CWA and possibly the federal ESA are not adequately enforced in portions of the country. Most of the objectives listed in the DEIS can be attained by enforcement of existing regulation, and OSMRE has an obligation to thoroughly analyze that set of alternatives.	Thank you for your comment. Please refer to Master Response on Alternatives.
OSM-2010-0021-0696	Murray Energy Corporation	The DEIS contains no matrix or table comparing all of the alternatives, which makes it difficult to compare the various components of each alternative. It is not clear what aspects of each alternative are similar or different.	Section 2.5 of the DEIS provides a comparison of the alternatives by functional group immediately following the detailed descriptions provided for each alternative.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.0.2.3, p. 4-7, last paragraph Without permit-specific requirements, OSMRE cannot characterize resources on such a broad scale to state that an alternative would be adverse or beneficial. Significant assumptions would need to be made, such as 1) the number of mines; 2) the length of time mines would operate; 3) the number of streams and stream types; and 4) the types of mitigation performed. Furthermore, OSMRE should clarify why sampling 25+ parameters provides a moderate benefit.	OSMRE appreciates the commenter's concern regarding the definitions of the impact characterization categories. We have more clearly defined the geographic scope and duration of the impact for each resource in section 4.0.3 and in resource-specific sections of chapter 4. The expanded definitions better articulate how impacts were determined for each resource in the FEIS. While there will certainly be expected variation in impacts of the Alternatives at a site-specific level, the overall effects of the actions have been evaluated for each resource on a regional scale. Increased monitoring provides better information for early identification of potential water quality impacts.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.1.3, p. 66, Table 4.2.1-6 The cited literature is entirely based in the Appalachian region. OSMRE fails to acknowledge that the environmental conditions in the Appalachian region are entirely different from conditions in other mining regions. OSMRE's approach is grossly simplistic and inappropriately generalizes surface water quality impacts on a nationwide basis.	OSMRE acknowledges that much of the research on understanding downstream effects of coal mining has been conducted in Appalachia. The history and extent of mining in the Appalachian Basin makes it the subject in the majority of the water quality studies (e.g., Lindberg et al., 2011, Merriam et al., 2011, Petty et al., 2010, Pond et al., 2008, Fulk et al., 2003). In addition, authors have also noted that due to the arid climate and high mineralization of stream water, analyses of this type are more difficult in western regions. Though limited,

ALTERNATIVES			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
			literature in other regions indicates similar downstream impacts despite obvious difference in geography. To account for these differences, model mines were developed to represent geography, coal production, and other environmental factors of each coal mining region.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.1.4, p. 4-72, "Streams degraded downstream of mining operations" bullet "It is especially difficult to provide context to estimates of miles where water quality is improved given the general nature of this indicator.... While state CWA section 303(d) water quality reports routinely identify coal mining as a pollution source, these data are not compiled at the regional level." Given the economic significance of the Proposed Rule, OSMRE should compile the regional data, and rely upon recent, actual data instead of data that are "typical" or outdated.	Please refer to Master Responses on Water Quality Benefits and Model Mines Analysis.
OSM-2010-0018-10447	Citizens Coal Council	OMSRE Should Choose the Most Protective Alternative in the DEIS. We support the analysis and conclusions in the Sierra Club, et al. (2015: III), and Foundation for Pennsylvania Watersheds (2015) comments relating to OSMRE's rejection of the alternative in the DEIS that would afford stronger stream protection requirements because they would adversely impact coal production. It is not the place of OSMRE to prop up an industry that is not only in structural decline and a net economic drain in Appalachia (Sierra Club, et al. (2015 III.A&B)), but also fails to internalize the costs created by its contributions to widespread public health problems in Appalachia and the public and private costs created by climate change (Sierra Club, et al., (2015: IIIC&D)). Coal mining should not take place at the expense of human health and the in violation of the requirements for environmental protection in SMCRA and other environmental laws. By adopting the most protective alternative in the DEIS, the environmental costs of coal mining will be further internalized, creating a more level playing field for the uses of less damaging energy sources.	Thank you for your comment. Please refer to Master Response on Alternatives.
OSM-2010-0021-0068	Earthjustice	OSMRE states in the preamble and DEIS that it considered alternative stream protection requirements that would have provided greater protection to streams, and rejected them	Thank you for your comment. Please refer to Master Response on Alternatives.

ALTERNATIVES			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		because they would interfere with coal production. In making this choice between alternatives, OSMRE has overlooked relevant and important considerations that support adoption of a more protective alternative. Choosing a less protective alternative without fully considering its costs is arbitrary and capricious and violates the National Environmental Policy Act (NEPA).	
OSM-2010-0018-10410	Tri-State Generation and Transmission Association	OSMRE should select the No Action Alternative in the DEIS or alternatively narrow the applicability of the rule to the specific stream-impact issues in the Appalachian Region.	Thank you for your comment. Please refer to Master Response on Alternatives.
OSM-2010-0021-0068	Earthjustice	OSMRE has legal tools at its disposal to improve enforcement of current stream protections, both through this rulemaking and by use of other authorities. Because OSMRE has ample authority to improve enforcement of the stream-channel protections that are currently in force, it has an obligation under NEPA to consider doing so as an alternative to a complete overhaul of the rule's stream-channel provisions.	Thank you for your comment. Please refer to Master Response on Alternatives.
OSM-2010-0021-0696	Murray Energy Corporation	Alternative 8 (Preferred Alternative)Section ES.5, p. ES-20, and Section 2.4.8.2The DEIS discusses returning the topography, vegetation, and characteristics of the original stream channels to pre-mining conditions, which is contrary to the scenarios portrayed in the Preferred Alternative. The construction of aquitards will decrease infiltration and increase runoff thereby altering the pre-mining site conditions. OSMRE's requirement to create aquitards will alter the natural hydrology of the area.	No change required to the EIS text; there is no contradiction in the text sections discussed in the comment. Selective placement of aquitards (barriers to groundwater infiltration) within the backfill or fill when necessary to restore perennial and intermittent streams is not inconsistent with other requirements for restoration of natural hydrologic conditions. Construction of aquitards would restore the layer of lower-permeability near the surface but below the root zone for trees and shrubs that in pre-mining conditions provided the subsurface to perennial and intermittent stream segments, instead of allowing that flow to infiltrate the newly created fill.
OSM-2010-0021-0696	Murray Energy Corporation	Alternative 8 (Preferred Alternative) Section ES.5, p. ES-23, second and third paragraphs "The Preferred Alternative would make enhancement measures mandatory whenever the proposed operation would result in long-term adverse impacts to the environmental resources of a stream due to placement of excess spoil or coal refuse in a perennial or intermittent stream (but not ephemeral streams). Resource enhancement measures must be: (1) commensurate with	The two requirements are not in conflict. The first requirement pertains to placement of excess spoil or coal refuse in perennial or intermittent streams only, and requires the stated measures when this activity occurs. The second requirement is independent of the first. It requires a 100-ft width of streamside vegetation along each side of the stream

ALTERNATIVES			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		the long-term adverse impact to affected resources; and (2) located in the same or nearest adjacent watershed as the proposed operation if there are no opportunities for enhancement within the same watershed, and be on permitted area. Alternative 8 (Preferred) would require creation of a 100-foot riparian corridor, comprised of native non-invasive species, adjacent to all ephemeral, intermittent, or perennial streams within the permit area. The riparian corridor must be established along the entire reach of any stream restored or permanently diverted." In the first sentence, enhancement measures would be mandatory if there were long term impacts to the environmental resources of the stream due to placement of excess spoil or coal refuse in a perennial or intermittent stream, but not an ephemeral stream. However, a 100-ft riparian corridor is required on all ephemeral streams (DEIS, at ES-19). These two requirements contradict each other.	regardless of type.
OSM-2010-0021-0696	Murray Energy Corporation	Comparison of all Alternatives Considered Section ES.6, p. ES-30 Only Alternative 9 uses the words "natural channel design," while the descriptions of the other eight alternatives refer to "hydrologic form and ecological function," which is the terminology used by the Proposed SPR.	The term "natural channel design" refers to a specific methodology used to restore streams in a way that mimics natural conditions, supported by specific techniques such as those described in U.S. EPA's "Natural Cannel Design Review Checklist" in which streams are restored to mimic natural conditions. This is different than the requirement to demonstrate restoration of hydrologic form and ecological function specific to a particular stream reach. Alternative 9 proposed to require the use of the natural channel design methodologies, whereas the other alternatives required the restoration of form and function but not specifically through the natural channel design techniques.
OSM-2010-0021-0696	Murray Energy Corporation	The EIS states: *"The cumulative impacts analysis recognizes that in most cases the contribution to the cumulative impacts for a given resource from implementing the Action Alternatives is difficult to discern, at a broad programmatic level across the U.S., given the context and intensity of impacts from the other past, present, and future actions. In most situations, implementation of one of the Action Alternatives would likely help reduce long-term adverse impacts on the resource by providing a certain level of*	No change was necessary in response to this comment. The environmental consequences section already reflects the impact of mining under existing regulations, plus the impact of all other contributing factors on each resource, within the resource specific discussions of impacts (both beneficial and negative) from the no action alternative. As explained in the document the Action Alternatives were compared against the status quo of existing

ALTERNATIVES			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		offsetting benefits. This is especially true when the Action Alternatives are considered in combination with other actions of similar intent (e.g., point source discharge permitting, river conservation initiatives, etc.). For resources other than socioeconomics, the analysis concludes that Action Alternatives (except for Alternative 9) would have a "beneficial or countervailing cumulative effect," meaning that, in combination with other actions and trends, the Alternative is expected to result in either a net increase in beneficial impacts or a net reduction in adverse impacts to the resource. Alternative 9 is anticipated to have a neutral cumulative effect." Alternative 1 (No Action Alternative) should be included in this discussion, since the existing rules already have beneficial effect.	regulations to determine the differential impacts of mining under the existing regulations in comparison to mining under possible regulatory scenarios contained in the Action Alternatives. The differential impacts of the no action alternative in comparison to itself would be zero, and therefore there is no merit in interjecting this thought into the discussion of the cited paragraph.
OSM-2010-0021-0696	Murray Energy Corporation	Need for the Regulatory Improvements Section 1.1.1, p. 1-12 The alternatives contained in the DEIS reflect yet another failed approach by OSMRE to adequately and rationally implement sustainable restoration practices. OSMRE has failed to define what standard applies to the requirement that reconstructed streams "enhance fish and wildlife." OSMRE has not specified what conditions and metrics it will use to measure "environmental values."	Please see the proposed and final rule (§ 780.16 or § 784.16) for discussion of applicable standards for fish and wildlife enhancement requirements. Fish and wildlife enhancement measures are described in general for each alternative in Chapter 2 of the DEIS and FEIS, and summarized in Section 2.5.6.5.
OSM-2010-0021-0696	Murray Energy Corporation	The action alternatives considered in the DEIS address a narrow range of possible options for achieving OSMRE's goal of minimizing or avoiding impacts to streams from mining activity. The alternatives variably require buffering a stream with no mining in-stream or mining through a stream, and no other alternative approaches were evaluated. This limited range of alternatives is inconsistent with NEPA assessment requirements to examine a robust and representative range of plausible alternatives.	Thank you for your comment. Please refer to Master Response on Alternatives.
OSM-2010-0021-0696	Murray Energy Corporation	Section 2.0, p. 2-1 Where ephemeral and/or intermittent streams are present, a viable alternative would include diverting the stream around the mining area, allowing mining through the stream, and requiring restoration of the channel's functionality prior to rerouting water back into the restored channel. This would allow for greater ease of access to minerals while avoiding impacts to downstream beneficial uses. In some instances where few sensitive beneficial uses	No change required. The comment infers that the alternatives would prohibit mining through ephemeral and/or intermittent streams. However, mining would conditionally be allowed through perennial, intermittent and ephemeral streams under most of the alternatives including the no action alternative and the Preferred Alternative. The exceptions are alternatives 2, 4, and 7 which would prohibit mining through

ALTERNATIVES			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		are present, this approach would also be viable for perennial streams. OSMRE failed to consider this alternative in the DEIS.	perennial streams.
OSM-2010-0021-0696	Murray Energy Corporation	Section 2.0, p. 2-1 Chapter 2 discusses the development of the 9 alternatives as well as 3 alternatives that were rejected. The alternatives were discussed in light of the 11 principal elements in the regulations. OSMRE did not include an explanation of how each alternative was developed and what benefit would be expected. OSMRE also did not direct reviewers to a subsequent section explaining why Alternative 8 was chosen as preferred.	Thank you for your comment. Please see EIS Section 2.1 "Development of Alternatives" which provides a discussion of the history of the development of the alternatives considered. Reasons for selection of the final rule, aka the final version of the Preferred Alternative, as the Preferred Alternative will be included within the Record of Decision.
OSM-2010-0021-0696	Murray Energy Corporation	OSMRE made no attempt to include alternatives that might have improved the current rule without causing large increases in time and cost to complete a permit application.	Please see the RIA for discussion of cost impacts. The findings of the RIA do not indicate large increases in time or cost to complete the permit application.
OSM-2010-0021-0696	Murray Energy Corporation	Alternative 2 Section 2.4.2, p. 2-12, first paragraph Alternative 2 and the Preferred Alternative are fraught with compliance and permit issues that would have direct and significant impacts on federal, state, and tribal laws, including the challenge of complying with and enforcing them.	Without more specifics on the concerns we cannot specifically address this comment. However, OSMRE received and considered comments on the proposed rule (Preferred Alternative) regarding permitting and compliance issues. See the preamble to the final rule for responses addressing these comments.
OSM-2010-0021-0696	Murray Energy Corporation	Alternative 2 Section 2.4.2, p. 2-12 "Under Alternative 2, and all the Action Alternatives to follow, the proposed regulatory changes pertain to SMCRA only; implementation of any of the proposed Alternatives below would not affect compliance with any other federal, state or tribal laws." OSMRE is incorrect. As set forth in the Proposed SPR itself, the alternatives would affect compliance with federal, state, and/or tribal laws. The DEIS fails to identify which aspects of current regulations would be affected, requiring change to current state and tribal laws and waivers from other federal agencies. This impact is missing from the RIA as well.	No alternative proposes changes to any federal law other than SMCRA. The Proposed Action would necessitate change in state and tribal programs only to the extent required to meet the minimum standards imposed under the revised federal SMCRA requirements.
OSM-2010-0021-0696	Murray Energy Corporation	Revegetation, Topsoil, and Fish and Wildlife Protection and Enhancement Section 2.4.2.4, p. 2-18, first paragraph "Alternative 2 includes provisions similar to those of the No	Thank you for your comment. Alternative 2 would not establish mandatory post-mining land uses but would require restoration of the capability of the land to support uses it

ALTERNATIVES			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		Action Alternative with respect to soil management and revegetation, but with a greater emphasis on restoration of the site's ability to support the uses it supported before any mining, regardless of the approved postmining land use" This provision of Alternative 2 is unrealistic and contrary to the spirit of SMCRA. Most states recognize the environmental and economic value in a range of post-mining land uses and the landowner's rights to implement land uses that are approved and properly implemented. Mandatory post-mining land use requirements are unnecessary and may not be in the best interest of the environment and local communities.	supported before mining. While your comment here is directed towards Alternative 2 these same considerations apply to the Preferred Alternative. Therefore, please see the discussion of this topic in the preamble to the proposed rule and final rule; we have made changes to this aspect of the rule in response to public comments. We have not however made these changes to Alternative 2. Alternative 2 contains elements that are intentionally more protective of the environment.
OSM-2010-0021-0696	Murray Energy Corporation	Revegetation, Topsoil, and Fish and Wildlife Protection and EnhancementSection 2.4.2.4, p. 2-19, first paragraphThe requirement to salvage and redistribute all organic matter does not take into account the time and cost to process and resize large materials (tree trunks, branches, logs, etc.) that may not be needed for restoration. Instead, OSMRE should allow, as with Alternatives 3 and 5, that a qualified ecologist or similar expert would determine the amounts of organic matter needed to promote reestablishment of native vegetation and soil flora and fauna.	Alternative 2 contains elements that are intentionally more protective of the environment. OSMRE disagrees that the suggested change is necessary.
OSM-2010-0021-0696	Murray Energy Corporation	Alternative 3 Section 2.4.3, pp. 2-19 to 2-20, last paragraph OSMRE fails to provide a clear summary of the differences between alternatives relative to the four functional groups. This summary should be provided at the beginning of each new alternative description, so that it is clear how the alternatives differ.	No change required. Section 2.5 provides a comparison of the nine alternatives by functional group.
OSM-2010-0021-0696	Murray Energy Corporation	Revegetation, Topsoil, and Fish and Wildlife Protection and Enhancement Section 2.4.7.4, p. 2-33 to 2-34, last paragraph "Under Alternative 7, for areas subject to the enhanced permitting requirements, the regulatory authority may prohibit mining of areas where high value habitats are present. All other requirements for fish and wildlife protection and enhancement within these areas would be the same as Alternative 3 (see Fish and Wildlife Protection and Enhancement section for Alternative 3) except that under Alternative 7 the required riparian corridor width would be 100 feet versus 300 under Alternative 3." Under Alternative 7, for areas subject to the enhanced	Thank you for your comment. The meaning of the text is the same; the slight differences in wording are unintended and the proposed requirements were analyzed in the same manner across the applicable alternatives.

ALTERNATIVES			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		permitting requirements, OSMRE assumes the regulatory authority may prohibit mining of areas where high value habitats are present. It is unclear how, or if, this differs from similar statements for Alternatives 3 and 6, i.e., "would allow the regulatory authority to prohibit mining of high-value habitats within the proposed permit area." OSMRE fails to explain the difference between "may prohibit" and "would allow . . . to prohibit." OSMRE should also clarify the difference between "where high value habitats are present" and "high-value habitats within the proposed permit area."	
OSM-2010-0021-0696	Murray Energy Corporation	Alternative 9 -2008 Stream Buffer Zone RuleSection 2.4.9, p. 2-40"Alternative 9 is identical to the 2008 SBZ rule, which was vacated by court order on February 20, 2014. See 79 FR 76227-76233 (Dec. 22, 2014)."Alternative 9 is not an appropriate alternative to consider in the DEIS, given that the 2008 SBZ was rejected by the courts and by OSMRE as deficient and contrary to federal law in several aspects. The addition of this Alternative appears to be an attempt to falsely convey the concept that the 2008 SBZ represents the current practice (No Action Alternative).	Alternative 9 would require the repromulgation of the currently vacated 2008 Stream Buffer Zone rule. This Alternative would require minimization of excess spoil generation, place limits on excess spoil fill capacity to match the anticipated amount of excess spoil to be generated, and prohibit mining activities in or within 100 feet of an intermittent or perennial stream unless the applicant demonstrates and the regulatory authority finds that avoidance is not reasonably possible. The model mines analysis indicates that the impacts of Alternative 9 would not differ significantly from those of the No Action Alternative because the Clean Water Act requirements and policies discussed in the Regulatory Impact Analysis for this rulemaking and the state AOC and excess spoil policies identified in Section 4.2.3.1 of this DEIS have effectively achieved implementation of this Alternative in Central Appalachia, which is the region in which the 2008 Stream Buffer Zone rule would have had its greatest impact if it had remained in effect. Therefore, if repromulgated, Alternative 9 would now have Negligible effects on socioeconomic resources evaluated in this DEIS.
OSM-2010-0021-0696	Murray Energy Corporation	Alternative Comparison Discussion Section 2.5, p. 2-43 There is little to no variation in the action alternatives, and OSMRE has not selected a reasonable range of alternatives along the spectrum of possible alternatives to comply with	Thank you for your comment. Please see the discussion of what constitutes a reasonable range of alternatives within the Master response on Alternatives.

ALTERNATIVES			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		NEPA. For example, Alternative 1 (no action) and Alternative 9 (2008 SBZ Rule) are claimed by OSMRE to be nearly identical, so as to question the appropriateness of including Alternative 9 in the DEIS.	
OSM-2010-0021-0696	Murray Energy Corporation	Section 2.5.3.2, p. 2-47, third bullet "Alternative 2 also prohibits placement of excess spoil within 100 feet of an intermittent stream (excess spoil placement is allowed in or near ephemeral streams). Under Alternative 2 disposal of coal mine waste in or within 100 feet of an intermittent or ephemeral stream is allowed;" These two sentences seem to contradict one another. OSMRE should clarify how excess spoil differs from waste. Here and throughout the DEIS, the alternatives are not clearly defined or consistently applied.	There is no contradiction because the text is talking about two different materials, "excess spoil" versus "coal mine waste". Excess spoil means spoil material disposed of in a location other than the mined-out area; provided that spoil material used to achieve the approximate original contour or to blend the mined-out area with the surrounding terrain in accordance with §§ 816.102(d) and 817.102(d) in nonsteep slope areas shall not be considered excess spoil. Coal mine waste means coal processing waste and underground development waste. 30 CFR 701.5.
OSM-2010-0021-0696	Murray Energy Corporation	Section 2.5.4.1, p. 2-50, first paragraph "(3) the total volume of flow during any season of the year would not vary (flooding potential cannot be altered)." OSMRE fails to recognize that water flow volumes vary throughout the year, especially seasonally.	Edits were made to clarify that the text was referring to vary from premining conditions and not between seasons. See section 2.5.4.1
OSM-2010-0021-0696	Murray Energy Corporation	Appalachian Basin Coal-Producing RegionSection 3.5.3.1, p. 3-151 (also Section 3.5.3.4, p. 3-178; Section 3.5.3.5, p. 3-186; Section 3.5.3.6, p. 3-193; Section 3.5.3.7, p. 3-199)For each mining region, OSMRE discusses all causes of stream impairment. OSMRE should clearly distinguish impairments attributable to mining from impairments and conditions attributable to other sources (i.e., non-mining sources). Only by doing so can the impact of the different DEIS alternatives be properly evaluated. This comment is applicable to all of the sections listed above.	The content within chapter 3 provides descriptions of the environment of the areas to be affected by the alternatives under consideration, as required by 40 CFR 1502.15. The existing state of streams in the action area is provided to meet the requirements of 40 CFR 1502.15 to "describe the environment of the area(s) to be affected or created by the alternatives under consideration." Discussion of mining specific impacts to streams is contained within chapter 4 in the discussion of environmental consequences from mining under the current regulations (the no action alternative) in comparison to mining under the alternative regulatory scenarios.
OSM-2010-0021-0696	Murray Energy Corporation	Effects of the Current Regulatory Environment (the No Action Alternative^ Section 4.2.2.1, p. 4-49, second paragraph OSMRE's statements do not recognize that there are a number of reasons that riparian zones do not or cannot	The requirement for a riparian zone 100 feet in width does not specify that the vegetation within the zone must be water loving. In responding to similar comments on the proposed rule (i.e. the Preferred Alternative or Alternative 8) we have clarified the following:

ALTERNATIVES			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		occur along specific stream reaches. Particularly in the west, streams that are incised or on bedrock may not have soil or hydrologic characteristics that support a riparian zone of a given width (e.g., 100 ft.).	that plantings in streamside vegetative corridors must include appropriate native hydrophytic vegetation, vegetation typical of floodplains, or hydrophilic vegetation characteristic of riparian areas and wetlands to the extent that the corridor contains suitable habitat for those species and the stream and the geomorphology of the area are capable of supporting vegetation of that nature. We also clarified that it was not required to plant hydrophytic or hydrophilic species within those portions of streamside corridors where the stream, soils, or climate are incapable of providing the moisture or other growing conditions needed to support and sustain hydrophytic or hydrophilic species. In these situations, you must plant the corridor with appropriate native species that are consistent with the baseline information concerning natural streamside vegetation included in the permit application, unless otherwise directed by an agency responsible for implementing section 404 of the Clean Water Act, 33 U.S.C. 1344.
OSM-2010-0021-0696	Murray Energy Corporation	Impacts of the No Action Alternative on Water Resources: Surface Water Effects Section 4.2.1.1, p. 4-49 This section addresses surface water effects of the No Action Alternative. The need for an action alternative should be based solely on current mining practices, as carried out under the No Action Alternative, not on historical mining operations.	No changes were necessary in response to this comment. The text is in fact recognizing that current mining practices are much improved over historic practices.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4, p. 4-1 This chapter describes in great detail the effects of the nine alternatives but does not explain the selection method for the contents of each alternative.	See the discussion of the development of alternatives in section 2.1 of the FEIS.
OSM-2010-0021-0696	Murray Energy Corporation	Action Alternatives and Potential Effects on Water Resources - Reduce Miles ofFilled StreamsSection 4.2.1.2, p. 4-58"Alternative 2, 4, 5, 6, 7, and 8 (Preferred) prohibit flat decks on top of excess spoil fills, which are allowed under the No Action Alternative and Alternatives 3 and 9." The prohibition of flat decks on top of excess spoil fills will not	No changes were necessary in response to this comment. These alternatives would require that the placement of excess spoil fill final surface configuration must be compatible with the surrounding terrain and generally resemble landforms found in the surrounding area.

ALTERNATIVES			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		help to reduce concentrated high flow during storm events. Flat decks graded toward the rear have proven to aid in the control of storm runoff, leading to less pond cleaning and reduced flooding potential, which is currently a requirement of SMCRA.	Additionally the rule (i.e. the Preferred Alternative) requires specifically that fills must be located on the most moderately sloping and naturally stable areas available but this is balanced against the requirement to analyze and mitigate off-site flood potential. Under these alternatives temporary flat decks during construction of the fill to control runoff and siltation as construction progresses would continue to be acceptable. As the fill nears completion, the size of the flat deck would diminish, and the final slopes outside of the diminishing deck would be in the process of being reclaimed, with final slopes being similar to those of the natural terrain. Runoff from these slopes, and the final slopes of the completed fill would be manageable, particularly if techniques such as those of the Forestry Reclamation Approach, are used (geomorphic reclamation would be beneficial as well), particularly given that the requirements for design and operation of downstream siltation and stormwater management structures would have accounted for the degree of slope.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.1.2, p. 4-59, third paragraph "Alternative 2 prohibits all variances from the requirements to return the mined area to its AOC." Prohibiting all AOC variances is not realistic, as it is not always possible to return a mined area to its AOC in Appalachia.	Under Alternative 2 the applicant would not be able to obtain a SMCRA permit for mining operations where it was impossible to return the mined area to AOC. OSMRE did not select this alternative due in part to the degree of impact this would have on the availability of coal for extraction. The Alternative remains reasonable however, and is therefore considered in the analysis.
OSM-2010-0021-0696	Murray Energy Corporation	The proposed limitations on AOC variances would have little effect in western jurisdictions where existing regulations and practice already provide a similar level of protection (see Mont. Admin. R. 17.24.308).	Benefits were determined through the model mine analysis, which used actual permit data from current mines to design and analyze thirteen "representative" model mining operations, which are categorized by region and size (tons of coal produced annually). The model mines represent actual operations that have been permitted and implemented under

ALTERNATIVES			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
			existing regulations at the state and federal level and therefore already take into account existing protections and benefits of existing regulations in the manner in which they are actually applied.
OSM-2010-0021-0696	Murray Energy Corporation	The proposed revegetation and reforestation requirements would have little effect in western jurisdictions where existing regulations and practice already provide a similar level of protection. The proposed riparian revegetation requirements would not be achievable on ephemeral and many intermittent and perennial streams in the West. Most western sites are not forested and would not be returned to forest.	The requirement for a riparian zone 100 feet in width does not specify that the vegetation within the zone must be water loving. In responding to similar comments on the proposed rule (i.e. the Preferred Alternative or Alternative 8) we have clarified the following: that plantings in streamside vegetative corridors must include appropriate native hydrophytic vegetation, vegetation typical of floodplains, or hydrophilic vegetation characteristic of riparian areas and wetlands to the extent that the corridor contains suitable habitat for those species and the stream and the geomorphology of the area are capable of supporting vegetation of that nature. We also clarified that it was not required to plant hydrophytic or hydrophilic species within those portions of streamside corridors where the stream, soils, or climate are incapable of providing the moisture or other growing conditions needed to support and sustain hydrophytic or hydrophilic species. In these situations, you must plant the corridor with appropriate native species that are consistent with the baseline information concerning natural streamside vegetation included in the permit application, unless otherwise directed by an agency responsible for implementing section 404 of the Clean Water Act, 33 U.S.C. 1344.
OSM-2010-0018-10336	Conservation Law Center	It is necessary to make the restoration of stream function a clearly separate requirement to differentiate the restoration requirements for ephemeral streams and intermittent/perennial streams. The DEIS notes that the proposed rule requires applicants to restore only the form of an ephemeral stream, not its function. The proposed rule requires applicants to restore both form and function in impacted perennial and intermittent streams. Therefore,	OSMRE acknowledges that the methodology for measuring ecological function is still a matter of scientific debate, including debate on the extent to which stream form can be used as a proxy for ecologic function. The definition of ecological function in the final version of the rule clarifies our intended meaning of the term; it is not a metric in and of itself and can be

ALTERNATIVES			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		using form as a proxy for function (replacing only a stream's form with the unsupported promise that the function will follow) would make the restoration requirements for ephemeral, intermittent, and perennial streams identical. OSMRE must clearly state that form is not a proxy for function to avoid conflating these requirements.	adapted and updated or adjusted as the methodology evolves. Moreover, this is a definition; other sections of the final rule, for example sections 780.19(c)(6) and 784.19(c)(6), specify how we require indicators of "ecological function" to be measured and explain that these measurements must be based on accepted field-based methodology.
NA	EPA	A possible addition to refining protections based on stream type would be to consider an approach similar to that presented in Alternative 4. This approach would apply additional environmental protections based on factors that the Regulatory Authority has determined require special consideration, ie., proposed activities in state-designated High Quality or Exceptional streams, operations in strata known to produce acid ofr toxic mine drainage, operations that would exacerbate conditions in watersheds already with impaired streams, etc. The EPa would like to work with OSMRE to determine whether this or similar effective provisions could be a meaningful addition to the Preferred Alternative.	EPA suggested that we consider adding to the Preferred Alternative a provision similar to the approach proposed in Alternative 4 where additional environmental protections (permitting requirements) would be applied by the RA in certain site-specific circumstances (e.g., operations in state-designated High Quality or Exceptional streams, operations in strata known to produce acid or toxic mine drainage, operations that would exacerbate conditions in watersheds already with impaired streams, etc.) regardless of the flow regime of the affected streams. In discussing this comment further with EPA the agency suggested a modification of the Preferred Alternative to authorize the RA to require any or all of the following when enhanced permitting design was warranted: 1. Additional detail in the analysis of the receiving watershed including the location and type of current and past disturbances in the watershed and other activities that may affect water quality; 2. Measured stream flows and recorded storm hydrographs to develop premining hydrologic models; 3. Modeling of seasonal groundwater fluctuations. Analysis of the correlation between groundwater fluctuations, precipitation events and groundwater quality; 4. Establishment of clear environmental goals for the proposed operation. Use of

ALTERNATIVES			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
			background data and a detailed mine plan to demonstrate how environmental goals would be achieved; 5. Development of reclamation goals specific to the proposed operation and the site conditions that would include planning for timely redistribution of topsoil and organics, contemporaneous plantings, and any related actions that would help reduce water quality degradation from the proposed operation; 6. Additional detail in the mine plan to show changes in 6-month increments, specific to disturbed and reclaimed areas, roads, sediment controls, topsoil storage, fills, Best Management Practices (BMPs) etc.; 7. Use of premining hydrologic models to assess flood potential and need for flood control, to project sediment loads and determine the design criteria for sediment control structures and need for temporary sediment controls; and/or 8. Use of on-bench ponds, where possible, in conjunction with in-stream ponds below placement of fill. Design of on-bench ponds to accommodate both a full sediment load and maintenance of a low permanent pool to allow recirculation from in-stream ponds as needed. We decided not to proceed with this suggestion because the Preferred Alternative already requires the majority of these measures for all operations, with the exceptions noted below. 1. (Required for all operations under Preferred Alternative) Additional detail in the analysis of the receiving watershed including the location and type of current and past disturbances in the watershed and other activities that may affect water quality; 2. Measured stream flows (Required for all operations under Preferred Alternative) and

ALTERNATIVES			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
			recorded storm hydrographs (not required) to develop premining hydrologic models(not required); 3. Modeling (Not required) of seasonal groundwater fluctuations. Analysis of the correlation between groundwater fluctuations, precipitation events and groundwater quality(Required for all operations under Preferred Alternative); 4. (Not required) Establishment of clear environmental goals for the proposed operation. Use of background data and a detailed mine plan to demonstrate how environmental goals would be achieved; 5. (Required for all operations under Preferred Alternative) Development of reclamation goals specific to the proposed operation and the site conditions that would include planning for timely redistribution of topsoil and organics, contemporaneous plantings, and any related actions that would help reduce water quality degradation from the proposed operation; 6. (Not required) Additional detail in the mine plan to show changes in 6-month increments, specific to disturbed and reclaimed areas, roads, sediment controls, topsoil storage, fills, Best Management Practices (BMPs) etc.; 7. Use of premining hydrologic models (models not specifically required) to assess flood potential and need for flood control, to project sediment loads and determine the design criteria for sediment control structures and need for temporary sediment controls (but the assessment is required for all operations under the Preferred Alternative); and/or 8. (Not required) Use of on-bench ponds, where possible, in conjunction with in-stream ponds below placement of fill. Design of on-bench ponds to accommodate

ALTERNATIVES			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
			both a full sediment load and maintenance of a low permanent pool to allow recirculation from in-stream ponds as needed.
NA	EPA	We also note that the Preferred Alternative does not include the establishment of evaluation thresholds, as are included in several other alternatives. Including thresholds or similar provisions in the Preferred Alternative would improve environmental protection by providing an objective early detection system that could prevent adverse impacts from developing to the point that they cause material damage, requiring more costly corrective measures. Doing so would nicely complement proposed data collection and analysis provisions before, during and after mining, which are considered in the majority of other alternatives.	Based on this and other comments received OSMRE added evaluation thresholds to the Preferred Alternative.
NA	EPA	Page 4-56, Table 4.2.1-1: While many of the alternatives (2, 3, 4, 5, and 8 [Preferred]) require additional monitoring during mining and reclamation, alternatives 5 and 8 have no associated evaluation threshold. Additional monitoring and data collection could be rendered ineffective without objective criteria describing when corrective actions are needed and what specific actions are required.	Based on this and other comments received OSMRE added evaluation thresholds to the Preferred Alternative. We have not however added evaluation thresholds to alternative 5.

3. NEPA Compliance

NEPA COMPLIANCE			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
OSM-2010-0021-0066	NMA	Although OSMRE's overarching goal for the SPR is to improve protection of the environment and to minimize the impacts of current and anticipated future mining practices, OSMRE has failed to adopt a scientifically rational approach to the current understanding of ecology across the many different ecoregions in the US where mining occurs. OSMRE also failed to adopt the basic impact analysis and mitigation strategy hierarchy as required by NEPA or a basic scientific approach to the evaluation of environmental impacts associated with each of the different EIS Alternatives.	OSMRE's analysis is compliant with NEPA requirements to evaluate impacts of the Alternatives on natural resources. For each natural resource, OSMRE evaluates the Affected Environment and the impacts of the Alternatives on that environment. Please refer to the Master Response on NEPA compliance.
OSM-2010-0021-0066	NMA	The DEIS targeted thresholds determinations for "no effect," as opposed to the standard practice in Federal regulations to examine implementation options and efforts that "avoid, minimize and/or mitigate" impacts... The intent to have no effect on the environment is simply not attainable; the absence of hydrologic, biota, or topographic effects, and complete restoration to premining conditions, is not attainable and will effectively eliminate mining in most of the US.	The commenter is misinterpreting the NEPA analysis. The commenter appears to assume that the analysis "intends" to find no effect. In fact, the analysis identifies a series of thresholds, including No Effect, Minor Effect, Moderate Effect, and Major Effect, to which anticipated impacts are measured. As such, the "no effect" determination would be assigned where the analysis finds that no effects are likely to occur.
OSM-2010-0021-0066	NMA	The DEIS did not provide a predictive analysis in sufficient detail to ascertain the nature, magnitude, duration (timing), extent (geographic distribution), level of confidence, and range of uncertainty of the predicted changes. This predictive information is found in the most basic NEPA documents. The ability of the environment to recover, or rebound, was largely ignored in the DEIS.	These factors were considered in the DEIS as well as the FEIS; however the FEIS has added additional detail to better articulate how determinations were made. Please refer to Master Response on NEPA compliance.
OSM-2010-0021-0056	Utah Mining Association	The DEIS fails to follow basic scientific methodology and NEPA protocol for determining impacts and, therefore, required mitigation.	The EIS follows NEPA's requirements. Please refer to Master Response on NEPA compliance.
NA	EPA	Page 4-7: We recommend that the "Scope of Impact" be more clearly defined, as "small, medium, large" geographic areas are too arbitrary for accurate impact characterization. We suggest use of more defined areas such as watershed scales (e.g., HUC 8, HUC 12) or Ecoregions (e.g. Level II, Level III). Use of population size and dollar amounts as size thresholds when considering impact on communities and economies, respectively, are also recommended.	OSMRE appreciates U.S. EPA's concern regarding the definitions of the impact characterization categories. We have more clearly defined the geographic scope and duration of the impact for each resource in section 4.0.3 and in resource-specific sections of chapter 4. The expanded definitions better define how impacts were determined for each resource in the FEIS.
OSM-2010-0021-	Murray Energy	Alternative 1 (No Action Alternative) Section ES.4, p. ES-9,	The commenter has misread the cited text. The

NEPA COMPLIANCE			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
0696	Corporation	last two sentencesMoreover, it is wholly inappropriate and contrary to OSMRE's obligations under NEPA to dismiss, without discussion, an analysis of the existing requirements, and thereby an analysis of the proposed requirements, on underground mining operations "for reasons of brevity"	DEIS contains an analysis of impacts to underground mining operations, it merely omits the citations to the underground mining regulations where these regulations are exactly the same as the analogous regulations for surface mining.
OSM-2010-0021-0696	Murray Energy Corporation	The DEIS departs from customary and required NEPA practices by comparing action alternatives against other action alternatives, instead of against the No Action Alternative. Further, the DEIS fails to identify a no action alternative with respect to underground mining. As a result, the consequences of the Proposed Rule to the nation's economy, mining communities, and environment are nearly impossible to discern with sufficient clarity and precision. This is a critical flaw of the DEIS.	The commenter is incorrect in suggesting that the alternatives are compared to each other rather than to the No Action Alternative in this EIS. As stated in Section 4.0.2.3, "the analysis examines the impacts of the Action Alternatives and the extent to which they would reduce or increase coal mining-related impacts on resources as compared to the No Action Alternative."
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.4.1, pp. 4-318 to 4-327 None of the affected Native American tribes elected to participate with OSMRE as cooperating parties during the preparation of the DEIS. OSMRE fails to acknowledge why Native American tribes chose not to participate.	The tribes did not indicate their rationale for declining to participate as cooperating agencies under NEPA but two (the Navajo and Crow) have chosen instead to conduct government to government consultation with OSMRE.
OSM-2010-0018-10055	Pennsylvania Coal Alliance	OSMRE did not comply with 43 CFR 46.230 because the agency did not adequately consider input from the state regulatory authorities tasked with reviewing the Draft Environmental Impact Statement.	Please see the Master Response on Cooperating Agency Involvement
OSM-2010-0021-0068	Earthjustice	OSMRE has apparently created new estimates of total direct stream impacts under the Stream Protection Rule and its alternatives, including the no action alternative. The DEIS includes tables that detail several of the results of this analysis, including stream miles preserved and improved under each alternative. 2015 DEIS at 4-70 to 4-74. Yet the DEIS fails to disclose the estimates of total direct stream damage that presumably underlie this analysis. Both NEPA and basic transparency require OSMRE to disclose this information to the public through the environmental impact statement.	As stated in the FEIS, absent nationwide data regarding the historical effects of coal mining on streams filled, mined through, or degraded, the EIS describes a number of region- or site-specific studies that evaluate these types of coal mining impacts on streams. This information provides context for understanding the baseline levels of impacts to streams from coal mining. In addition, in response to public comment, the FEIS includes summaries of USACE permit data regarding permitted wetland and stream impacts from coal mining, as well as OSMRE data describing numbers of new mine permits and associated acreage of the new mine permits from 2005 and 2015.
OSM-2010-0021-0696	Murray Energy Corporation	"CEQ's regulations implementing NEPA encourage agencies to "tier" their EISs to eliminate repetitive discussions of the	Thank you for the comment. The use of the term "tiering" here is incorrect and edits have been

NEPA COMPLIANCE			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		same issues and to focus on the actual issues ripe for decision at each level of environmental review (40 CFR 1508.20). Tiering allows OSMRE to incorporate, by reference, one or more analyses in previous EISs. Therefore, in this DEIS, when applicable and appropriate, OSMRE relies on and references analyses in the following EIS documents . . ."OSMRE's use of "tiering" to incorporate sections of previously performed EISs by reference is inappropriate. OSMRE is not "tiering" as the term has been defined under CEQ and DOI's regulations interpreting NEPA. (See 40 C.F.R. § 1508.28; 43 C.F.R. § 46.140.) OSMRE refers to tiering here in the context of incorporating prior EIS work by reference into the DEIS.	made.
OSM-2010-0021-0696	Murray Energy Corporation	OSMRE should make these prior EISs available for public review and should explain what specific information in these 30+ year old documents is carried forward to the current DEIS. Documents incorporated by reference in an EIS "must be readily available for review and, when not readily available, they must be made available for review as part of the record supporting the Proposed Action." 43 C.F.R. § 46.135.	The list of documents is larger than necessary; several of the documents are not referenced anywhere in later text and were in no way used in the discussion or analysis. These have been removed from the list for the FEIS. Information regarding what specific sections of the FEIS use information from these documents is provided for the remaining list items, see Section 1.0.3.1. These documents are available for public review through the OSMRE library at http://www.osmre.gov/resources/library.shtm.
OSM-2010-0021-0696	Murray Energy Corporation	"Other EISs prepared by or in cooperation with OSMRE contain information relevant to this DEIS. As appropriate, this DEIS incorporates by reference relevant information or analysis, or refers the reader to specific or general sections of those documents. Information from the documents listed below is specifically incorporated by reference into this DEIS:* U.S. Department of the Interior, Office of Surface Mining Reclamation and Enforcement (OSMRE). Comprehensive Impacts of Permit Decisions under Tennessee Federal Program,OSMRE-EIS-18, March 1985.* U.S. Department of the Interior, Office of Surface Mining Reclamation and Enforcement. ValidExisting Rights: Proposed Revisions to Section 522(e) of the Surface Mining Control andReclamation Act of 1977 and proposed rulemaking Clarifying the Applicability of Section 522(e)to Subsidence from Underground Mining, Final Environmental Impact Statement OSMRE-EIS-29, July 1999."Several concerns, criticisms, and deficiencies were noted at the	We are unable to address the comment in regard to the deficiencies alleged in EIS-18 and EIS-29 since the comment was non-specific. However these two documents were not referenced anywhere in the actual text of the DEIS and were in no way used in the discussion or analysis. We have removed these from the list of referenced documents in section 1.0.3.1.

NEPA COMPLIANCE			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		time these documents were released. OSMRE has not corrected these issues and deficiencies, nor has OSMRE addressed these criticisms in the DEIS. Therefore, OSMRE's reliance on this debated and potentially flawed document affects the technical quality and level of confidence in OSMRE's 2015 DEIS. Because OSMRE has not made the past EIS documents publicly available, commenters do not have access to the assumptions and supporting data that OSMRE has elected to adopt without disclosing in its current DEIS work.	
OSM-2010-0021-0696	Murray Energy Corporation	OSMRE failed to properly include minority populations and environmental justice communities in the development of the Proposed Rule. OSMRE did not hold open houses in several important mining states. OSMRE also did not follow guidance by the CEQ regarding specialized, targeted methods of engagement for minority populations (CEQ, 1997). Moreover, OSMRE should have held a higher proportion of public meetings in the areas identified in the DEIS of minority populations (see DEIS, at 4-232, 4-240, and 4-328).This failure to adequately engage minority populations is demonstrated by the fact that only 1,328 comments of the total 20,571 received addressed the socioeconomic effects of the Proposed Rule. Moreover, the fact that a mere 400 people attended across all 9 open houses demonstrates the ineffectiveness of OSMRE's public outreach strategy.	OSMRE complied with all APA and NEPA requirements, as well as the requirements of Executive Order 12898, regarding Environmental Justice in Minority Populations and Low-Income Populations. The comment is incorrect in stating that we did not follow the 1997 CEQ Environmental Justice Guidance Under the National Environmental Policy Act. Section III of the Guidance recommends that agencies should follow six principles for considering environmental justice under NEPA. The public meeting strategy, the DEIS and the RIA addressed each of these as indicated below. - Determine whether minority populations, low-income populations, or Indian tribes are present in the area affected by the Proposed Action, and if so whether there may be disproportionately high and adverse human health or environmental effects on minority populations, low-income populations, or Indian tribes. - Consider relevant public health and industry data concerning the potential for disproportionately high and adverse human health of environmental effects on minority populations, low-income populations, or Indian tribes from the action. - Consider interrelated cultural, social, occupational, historical, or economic factors that may amplify the natural and physical environmental effects of the action. - Develop effective public participation strategies. Agencies should, as appropriate, acknowledge and

NEPA COMPLIANCE			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
			seek to overcome linguistic, cultural, institutional, geographic, and other barriers to meaningful participation and should incorporate active outreach to affected groups. - Assure meaningful community representation. - Seek tribal representation consistent with the government– to–government relationship between the United States and tribal governments, the federal government's trust responsibility to federally recognized tribes and any treaty rights. Section 4.4 of the EIS and Section 9.3 of the RIA provide analysis and discussion in accordance with these principles. Of the 286 counties in the study area, there are 190 counties that have populations that meet the previously specified low income and/or the minority population environmental justice thresholds. Of these 190 counties, 60 percent of them are in the Appalachian Basin. Of those counties in the Appalachian Basin, four have been identified as minority communities, 103 as low income communities, and nine as both low income and minority environmental justice communities. It was therefore impracticable to hold a public meeting in each of the coal-producing counties that met one or both of the environmental justice criteria.To ensure effective public participation and meaningful community representation OSMRE operated the public meetings with a professionally developed meeting plan including accommodations for hearing impaired participants, multiple written and oral means of comment submittal, Navajo translators, and carefully selected venues to provide free and convenient access. OSMRE ensured broad and effective outreach by releasing information to news outlets, through social media (Twitter and Facebook) in addition to posting information on our website and publication through the Federal Register. OSMRE's efforts to conduct government-to-government consultation are discussed in Chapter 5 of the FEIS.

NEPA COMPLIANCE			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
OSM-2010-0021-0696	Murray Energy Corporation	Given the expansive geographic area that the Proposed Rule covers and the potential for differing opinions on how the proposed alternatives affect certain sectors of the public, OSMRE's public involvement strategy was insufficient and a direct violation of NEPA.	Thank you for your comment. The public meetings were conducted in accordance with CEQ NEPA regulations and the OSMRE NEPA handbook. OSMRE conducted six public hearings in Colorado, Kentucky, Missouri, Pennsylvania, Virginia and West Virginia during the public comment period. Ultimately, OSMRE received approximately 95,000 comments, including hundreds of pages of comments from state SMCRA regulatory authorities, on the DEIS and the proposed stream protection rule.
OSM-2010-0021-0696	Murray Energy Corporation	Development of the AlternativesSection 2.1, p. 2-3, second paragraphThe lack of transparency regarding the evolution of OSMRE's approach to drafting the EIS based on public comments and input from stakeholders undermines confidence in the DEIS. OSMRE should appropriately explain specifically how it responded to concerns and suggestions provided by stakeholders.	All comments received on the proposed rule, the Draft RIA, and the DEIS are available for review on regulations.gov. Responses to the comments are made through the preamble to the final rule, or in the appendices of the RIA and EIS.
OSM-2010-0021-0696	Murray Energy Corporation	Development of the Alternatives Section 2.1, p. 2-3, second paragraph OSMRE should provide public access to the record of work and the public comments collected by OSMRE in prior public notices and comment periods.	All public comments received on the proposed rule, the Draft RIA and the DEIS are available on regulations.gov. Similarly all public comments received on the final documents will be available on regulations.gov. OSMRE is maintaining an administrative record for the project and will provide materials upon request through the Freedom of Information Act as appropriate.
OSM-2010-0021-0696	Murray Energy Corporation	Activities in or Near Streams Section 2.4.1.2, p. 2-7 This section particularly, and the entire DEIS more generally, ignores the alluvial valley floor regulations, which address many of the issues related to mining in and near streams. OSMRE should acknowledge, and evaluate its Proposed Rule in consideration of these regulations.	The regulations associated with alluvial valley floors are limited by definition to operations in areas of the arid or semi-arid southwest with water availability sufficient for subirrigation or flood irrigation. The SPR makes no changes to the regulations pertaining to these operations, other than edits to the discussion of permit renewals involving alluvial valley floor variances within 774.15(c)(3) for simplification to adhere to plain language principles. No aspects of the alluvial valley fill regulations in 30 CFR 789.15 or 30 CFR Part 822 would be contradicted or superseded by the requirements of the SPR; neither do the requirements of the alluvial valley fill regulations make the SPR requirements unnecessary.
OSM-2010-0021-	Murray Energy	Topography	The source document for these photographs is

OSM-2010-0021-0696	Murray Energy Corporation	Water Usage Overview Section 3.5.2.4, p. 3-143 OSMRE states that the information in Table 3.5-5 of the DEIS describing water usage information compiled by the USGS will be changed in the final version of the EIS to reflect more recent USGS 2010 water usage data. OSMRE should provide an opportunity for public comment after the USGS 2010 water-usage data are included in the EIS	OSMRE has updated the data (see section 3.5) in the FEIS. The updated data is not so substantively different as to invalidate the analysis performed for the DEIS, and does not warrant reissuance of the DEIS for additional public comment.
OSM-2010-0021-0696	Murray Energy Corporation	Additionally, OSMRE should indicate whether any other parts of the DEIS are anticipated to change after the public comment period ends, and whether OSMRE intends to make the revised DEIS available for public comment prior to finalization.	The FEIS contains edits as described here in the response matrix. The FEIS, rule and RIA will all be publicly available upon issuance. There is no legal requirement to reinitiate public comment on the final versions of these documents.
OSM-2010-0021-0696	Murray Energy Corporation	*Section 5.0, p. 5-1To comply with the National Environmental Policy Act (NEPA), and Council on Environmental Quality (CEQ), and Department of Interior regulations implementing NEPA, the Office of Surface Mining Reclamation and Enforcement (OSMRE) has consulted and coordinated with federal and state agencies, organizations, tribes, interested groups, and individuals during the development of the Proposed Action and this Draft Environmental Impact Statement (DEIS).*The record is clear that OSMRE barely consulted or coordinated with the states causing state agencies to withdraw their involvement in the DEIS work. Consequently, OSMRE cannot claim that stakeholders were included in the consultation and coordination process under NEPA related to the development of action alternatives. Most state agencies withdrew their support as a last effort to encourage OSMRE to pay attention to their concerns. Failure to include cooperating state agencies, and particularly those states with clear regulatory authority, is a violation of NEPA.	Please refer to Master Response on Cooperating Agency Involvement.
OSM-2010-0021-0696	Murray Energy Corporation	*Section 5.2, p. 5-3OSMRE retained the comments received previously from the cooperating agencies and ensured that they were considered during the preparation of the current DEIS. These comments were very informative as to*	Please refer to Master Response on Cooperating Agency Involvement.

NEPA COMPLIANCE			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		*the scope and content of the analysis needed for the DEIS. The current DEIS retains very little content from the original preliminary draft; however, OSMRE considered those comments in revising the Alternatives, methodology and content of the current DEIS.*Several states that initially participated as cooperating agencies on the preliminary DEIS in 2010-2011 subsequently withdrew their participation because OSMRE provided insufficient time for review and comment, failed to provide promised documents, and failed to identify how state comments were addressed in the preliminary DEIS. When OSMRE restarted its efforts on the current DEIS in the fall of 2011, it did not reengage the states as cooperating agencies. OSMRE indicates that it "retained the comments received previously from the cooperating agencies and ensured that they were considered during the preparation of the current DEIS." It is unclear, III-302 Draft Environmental Impact Statement however, what information from the 2010 efforts has made its way into the current DEIS. The cooperating states have not been consulted during development of the current DEIS, as is evident by the application of a one-size-fits-all approach versus consideration of state and regional differences with respect to which the states are in the best position to speak.	
OSM-2010-0021-0696	Murray Energy Corporation	*Section 5.4, p. 5-4*OSMRE's public involvement process failed to meet NEPA requirements for fully informed and participatory stakeholder engagement. Two comment periods—30-day and a 45-day— were heldin 2010, and 9 scoping open houses equally distributed across AL, IL, IN, TX, NM, WY, KY,and WV were also held. The open houses did not include several important mining states.OSMRE's application of CEQ guidance on the criteria to establish an "environmental justice"(EJ) community clearly identifies that the majority of the EJ communities are in Appalachia,Illinois Basin, and Northern Rocky Mountains and Great Plains (tables on pp. 4-319 to 4-322).Standard publication methods (Federal Register, local newspapers, poster stations at openhouses) were used. CEQ guidance specifically spells out the need for specialized, targeted engagement of minority populations (CEQ pp. 4, 9, and 11) and lists a variety of suggestedmethods. Not only were these methods not used, distribution of minority	Thank you for your comment. The public meetings were conducted in accordance with CEQ NEPA regulations and the OSMRE NEPA handbook. In addition to the scoping related comment periods in 2010 OSMRE conducted six public hearings for the DEIS in Colorado, Kentucky, Missouri, Pennsylvania, Virginia and West Virginia during a 102-day public comment period. Ultimately, OSMRE received approximately 95,000 comments, including hundreds of pages of comments from state SMCRA regulatory authorities, on the DEIS and the proposed stream protection rule.

NEPA COMPLIANCE

COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		populations (DEIS pp.4-232 to 4-240 and 4-328) suggests that a proportionally higher number of meetings should havebeen held in these areas. Out of more than 20,000 comments, only 1,300 addressedsocioeconomics, even though all alternatives will have some adverse effect on socioeconomics.This reinforces the possibility that affected populations were underrepresented in the commentIII-303 Draft Environmental Impact Statement period. The fact that only 400 people attended across all 9 open houses also suggests theineffectiveness of OSMRE's outreach and inclusion.	
OSM-2010-0021-0696	Murray Energy Corporation	Section 5.4, p. 5-4OSMRE's public involvement process in the formative stages of the DEIS was not consistent with NEPA requirements pertaining to outreach to stakeholders potentially affected by the Proposed Rule. OSMRE held 9 public meetings in 8 states representing 5 of the 7 coal regions. OSMRE did not encourage or facilitate public involvement in the 2 coal regions (northwest and western interior) and the other approximately 19 states with coal reserves. OSMRE fails to explain why its public outreach approach was representative of stakeholders in different regions where mining occurs throughout the U.S. OSMRE ignored the large geographic area addressed by the Proposed Rule and the potential for differing opinions on how alternatives affect certain regions and public and private sectors. OSMRE fails to explain its basis for the approach to public involvement, particularly in view of the seemingly small sample size of public opinion collected from its efforts.	Thank you for your comment. The public meetings were conducted in accordance with CEQ NEPA regulations and the OSMRE NEPA handbook. OSMRE conducted six public hearings in Colorado, Kentucky, Missouri, Pennsylvania, Virginia and West Virginia during the public comment period. Ultimately, OSMRE received approximately 95,000 comments, including hundreds of pages of comments from state SMCRA regulatory authorities, on the DEIS and the proposed stream protection rule.
OSM-2010-0021-0696	Murray Energy Corporation	Section 5.4, p. 5-4 Neither the ANPR (11/30/09) nor either NOI (4/10/10 and 6/18/10) provided adequate notice of various provisions OSMRE ultimately included in its Proposed Rule. For example, no notice was given that there would be any additional fish and wildlife enhancement requirements, including stream restoration. The notices only referenced possible requirements for reforesting previously wooded areas. These provisions go far beyond the public notice provided by OSMRE and precluded the public from having an opportunity to comment on proposed regulations that could dramatically impact mining operations and regulators.	As the lead agency OSMRE is ultimately responsible for determining the scope of the environmental impact statement. The NOI is published very early in the process, even before the scoping process is conducted, in compliance with 40 CFR 1501.7. The scoping process provides, among other things, the opportunity for participants to identify concerns, potential impacts and relevant effects of past actions and possible alternative actions. Scoping is therefore done very early in the process before the analysis or deliberations of the results have occurred; it is therefore a natural and expected outcome of the

NEPA COMPLIANCE			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
			NEPA process that the Proposed Action and alternatives would change between the earl identification provided at scoping. The input received during scoping efforts is important to help define the issues for consideration; however suggestions obtained during scoping are not binding but are only important options for the lead agency to consider. 43 CFR 46.235(b).
OSM-2010-0021-0696	Murray Energy Corporation	OSMRE's analysis lacks quantitative integrity and is, at best, a screening-level qualitative analysis of mining impacts. OSMRE's repeated use of terms like "quantitative" in the DEIS have important connotations in science and specific meaning in the NEPA process, to which OSMRE does not adhere.	As the comment notes, the analysis additionally evaluates the environmental improvements associated with the effect of the rule in reducing overall coal production. While the purpose of the rule is not to reduce coal production, our analysis finds that the rule has the unintended effect of marginally reducing coal production on the order of a fraction of a percent. Consistent with guidance provided by OMB in conducting regulatory impact analysis (as described in Circular A-4, 2003), the analysis evaluates these ancillary Benefits (and costs) of reductions in coal production alongside the direct Benefits (and costs) of the rule. It would be inappropriate to evaluate the unintended costs of the rule in reducing coal production without also considering the associated Benefits.

4. Cumulative Impacts

CUMULATIVE IMPACTS			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
OSM-2015-0002-0008	Natural Resource Partners LP	The Proposed Rule and accompanying analyses do not adequately address the scope and significance of the impacts on the human environment given OSMRE's originally description of its effort as a minor regulation confined to one region; in addition to a plethora of new rules which apply in every coal producing state, the Proposed rule amends or modifies at least 475 existing rules.	The Final RIA and FEIS for the SPR consider a number of recent U.S. EPA regulations as part of the baseline for the analysis. These are articulated in Chapter 3 and Appendix F of the RIA. These are also discussed in the cumulative impact analysis in section 4.5 of the FEIS. The Final RIA and FEIS baselines have been updated since the DEIS was released to the public.
OSM-2015-0002-0036	Anonymous	The CIA did not provide cumulative impact assessments of Alternative 1 (no action alternative).	The cumulative impacts analysis has been revised to more explicitly consider the impacts of the No Action Alternative on resources.
OSM-2015-0002-0036	Anonymous	It appears this [cumulative impacts assessment of No Action Alternative] was skipped because it would have shown the same Benefits of the rest of the proposals as the existing and proposed regulations have been and will continue to benefit these resources in a positive manner, even without this rule.	The cumulative impacts analysis has been revised to more explicitly consider the impacts of the No Action Alternative on resources.
OSM-2015-0002-0073	Peabody Energy	OSM's attempt to quantify cumulative impacts using potential job loss as a proxy for all socioeconomic impacts is also inadequate. Initially, as noted by NMA, the agency's statements about the impacts of the Proposed Action and the alternatives on jobs is wrong and unsupported. But further, as NMA also suggests, socioeconomic impacts from draconian regulations that devastate industry will run far deeper into coal mining communities.	The commenter is not correct that potential job losses are used as a proxy for all socioeconomic impacts. Section 4.3 of the EIS, Social and Economic Resources, considers potential impacts of the Alternatives on socioeconomics, land use, utilities, infrastructure, visual resources, noise, recreation, and public health and safety. Within the category of socioeconomics, section 4.3.1 of the EIS considers potential impacts of the Alternatives on income, tax revenues, property values, quality of life, and demographics in addition to consideration of potential impacts associated with employment. Please refer to Master Response on Alternative Analysis Provided by the National Mining Association in response to the commenter's discussion of NMA's analysis of job effects.

CUMULATIVE IMPACTS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
OSM-2015-0002-0060	Society for Mining, Metallurgy & Exploration	OSMRE does not demonstrate in the proposed Stream Protection Rule that a HUC-12 watershed as a minimum size is the best choice for the cumulative impact area in all regions of the country. We believe it would be more appropriate to determine the cumulative impact area based on conditions at the mine site that consider site-specific conditions.	Thank you for your comment. We appreciate that conditions can vary from mine to mine. However, Due to the broad geographic scope and timeframe for the analysis, we were unable to forecast conditions at every future mine site as part of this national-scale EIS. The 13 model mines across the seven major coal regions were developed in order to capture regional variability in terms of mining methods as well as regional context as much as was feasible.
OSM-2010-0021-0015	Anonymous	The cumulative effects analysis will lead you to believe the proposed rule would be positively beneficial to the industry. Further evaluation of cumulative impacts to public welfare and loss of jobs, wages, severance tax revenue, etc. must be assessed for each region that will be impacted.	An evaluation of the regional employment impacts associated with the SPR and its alternatives is presented in section 4.3.1.3 of the EIS (Employment Impact Analysis) as well as Chapter 6 of the RIA. In addition to employment, section 4.3.1 of the EIS considers potential impacts of the Alternatives on income (wages), tax revenues (including severance taxes), property values, quality of life, and demographics. Section 4.5.3 of the EIS (Assessment of Cumulative Impacts) discusses the impacts of the proposed rule and its alternatives together with ongoing trends specifically as related to ongoing trends in coal industry employment. The socioeconomic implications of the Action Alternatives are characterized as resulting in minor to moderate adverse impacts. The cumulative impact of the Action Alternatives on Socioeconomics, when combined with other actions and trends, is classified as negative.
OSM-2010-0021-0015	Anonymous	Broad cumulative impacts to socioeconomics have already occurred throughout these regions. Further analysis should be conducted on the livelihood of those who will lose jobs in these areas and the hardships their families will encounter. With already high poverty rates the cumulative effects on these areas would be significant.	Thank you for your comment. Section 4.3.1 of the EIS evaluates potential impacts of the SPR on employment, regional income, property value, tax revenues, and quality of life.
OSM-2010-0021-0015	Anonymous	Case law applying NEPA's cumulative impacts analysis requirement often addresses the question of whether a potential future action is "reasonably foreseeable" and therefore must be considered in the cumulative impacts analysis. The DEIS did not assess the cumulative impacts of	A discussion of U.S. EPA's recent Clean Water Rule to increase the clarity of waterway definitions of the waters of the U.S. under the Clean Water Act has been added to the cumulative impacts analysis. We note that rule

CUMULATIVE IMPACTS			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		the proposed rule with the new "waters of the U.S." rule that is also being put forth at this time. This rule was "reasonably foreseeable" and is not even considered in the assessment.	was stayed on October 9, 2015 by the U.S. Court of Appeals for the Sixth Circuit and is awaiting further action.
OSM-2010-0021-0038	Anonymous	There is no discussion of the cumulative impacts of additional job losses to these areas, particularly Appalachia. The proposal will take areas that are many times below the poverty level, and decrease overall income for the household, local, county, and states.	Thank you for your comment. Section 4.3.1 of the EIS evaluates potential impacts of the SPR on employment, regional income, property value, tax revenues, and quality of life.
OSM-2010-0021-0061	Peabody Energy	In the DEIS, OSMRE identified a number of past, present, and reasonably foreseeable actions directed at regulating, or that will indirectly impact, the coal mining industry. See DEIS 4-334 to 4-337. Even assuming this list is complete, which it is not, OSMRE makes no attempt to evaluate or quantify the social and economic impact of these regulatory actions on the industry. Instead, after listing these actions, it simply concludes without analysis that the coal mining industry faces regulatory and non-regulatory challenges that could impact the industry negatively. That is not a sufficient basis upon which to conduct a cumulative impacts analysis.	As stated in Section 4.5.1 of the EIS, the diverse set of affected resources, combined with the broad geographic and temporal scope of the SPR, makes cumulative impact analysis highly challenging. Indeed, simply identifying the full suite of past, present, and future actions affecting water resources in coal mining areas in the U.S. under the No Action Alternative and Action Alternatives is not feasible. For example, dozens, if not hundreds, of federal, state, and local laws and regulations could be perceived as being relevant to protecting the quality of water resources in streams affected by mining. Furthermore, an array of individual projects (e.g., dam construction, dredging), permitting decisions, and economic trends could further influence water quality. Identifying and accounting for all of these factors is not practical, and prediction of cumulative impacts based on such an approach would be speculative. Because it is practically infeasible to characterize every potentially relevant cumulative action in all coal-producing areas in the U.S., the analysis focuses on identifying the primary actions – particularly those that may combine with the Alternatives to produce noteworthy cumulative effects. This approach is consistent with CEQ guidance, which states that "a cumulative effects analysis should 'count what counts,' not produce superficial analyses of a long laundry list of issues that have little relevance to the effects of the Proposed Action on eventual decisions" (CEQ,

CUMULATIVE IMPACTS			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
			1997). The analysis recognizes that under the No Action Alternative, coal production is anticipated to decline, which could have adverse effects on communities that depend on coal production. The analysis finds that the Action Alternatives have some potential to exacerbate this effect. A quantitative evaluation of this effect is not required by NEPA.
OSM-2010-0021-0061	Peabody Energy	OSMRE then adds its conclusion that Alternative 2 will have a "moderate adverse" impact on social and economic resources and that the rest of the alternatives will have "minor adverse" impacts to its unsupported conclusion about the impact of existing and foreseeable regulatory actions and trends to find that the cumulative effect of the SPR on social and economic resources will be "negative." This one word conclusion is not only unsupported in the DEIS, but wholly inadequate to inform OSMRE of the cumulative impacts of its Proposed Action and its alternatives. The DEIS, therefore, provides the agency no context, quantifiable or otherwise, of the cumulative impacts of its proposal.	A quantitative evaluation of the regional employment impacts associated with the SPR and its alternatives is presented in section 4.3.1.3 of the EIS (Employment Impact Analysis) as well as Chapter 6 of the RIA, which also includes a presentation of the impacts of the SPR on employment compensation. Section 4.5.3 of the EIS (Assessment of Cumulative Impacts) discusses the impacts of the proposed rule and its alternatives together with ongoing trends specifically as related to ongoing trends in coal industry employment. The FEIS has been updated to provide additional contextual information to assist the reader in understanding the potential implications of the SPR on employment. Specifically, the EIS in Section 4.5.3.5 recognizes that under the No Action Alternative, coal production is anticipated to decline, which could have adverse effects on communities that depend on coal production. The analysis finds that the Action Alternatives have some potential to exacerbate this effect. A quantitative evaluation of this effect is not required by NEPA.
OSM-2010-0021-0070	Luminant Mining Company LLC	In essence, OSMRE estimates that the job losses caused by the Proposed Rule will be minor because industry jobs are disappearing anyway. It therefore treats the anticipated job decline as part of the baseline, and concludes the effects of the Proposed Rule will be insignificant. This is inappropriate, and does not comply with NEPA. Instead, as explained below, OSMRE must treat the anticipated job losses as cumulative socioeconomic impacts resulting not	The commenter is incorrect in stating that the EIS "assumes that job effects of the rule are minor because industry jobs are disappearing anyway." First, findings about socioeconomics impacts of the rule in section 4.3.1 of the EIS include consideration of the scope and scale of impacts on individuals, groups, businesses, properties, or institutions. Findings vary by

CUMULATIVE IMPACTS			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		only from the Proposed Rule but also from all of the other rules this Administration has imposed and is currently imposing on the coal industry, discussed in detail below. OSMRE must evaluate the cumulative socioeconomic impacts of all of the past, present, and reasonably foreseeable federal actions affecting the coal industry and the communities and businesses that rely on coal, which are contributing to the drastic and nationally, regionally, and locally significant job losses and adverse socioeconomic impacts. [..] OSMRE is cynically attempting to rely on other federal rules that adversely affect the coal industry to support its conclusion that the job losses from the Proposed Rule are insignificant, without ever having done a proper cumulative impacts analysis of all of these federal actions affecting the coal industry, as required by NEPA.	region, but include overall findings that Major Adverse impacts on socioeconomic resources may occur as a result of several Alternatives. The Proposed Acton Socioeconomic Resources ion is anticipated to result in Moderate Adverse impacts at the national scale. The cumulative impacts analysis discusses the ongoing trends in the coal market and coal market employment, and concludes that these impacts "would be added to existing and anticipated adverse conditions in the coal mining industry, and could exacerbate these declining conditions."
OSM-2010-0021-0070	Luminant Mining Company LLC	While OMSRE considered some of the regulations and federal actions that have a cumulative impact, the analysis excludes several important actions taken by federal agencies targeting the coal mining industry, the impacts of which must be fully analyzed under NEPA. The DEIS includes Clean Water Act ("CWA") Section 404 in its list of "Past and Present Actions," however the DEIS does not include in its analysis the cumulative impacts associated with the limits on the use of Nationwide Permit 21 ("NWP 21"). OSMRE has proposed to adopt, by cross-reference, the U.S. EPA/Corps definition of "waters of the United States" into its SMCRA regulations. The DEIS does not consider the impacts of this recent rule despite the fact that it will have a significant impact on the coal industry and on the implementation of the Proposed Rule.	Thank you for your comments. Nationwide Permit 21 is discussed in section 4.2.11 of the EIS. Consideration of this permit has been incorporated into the Cumulative Impact Analysis in Section 4.5 of the EIS. A discussion of U.S. EPA's recent Clean Water Rule to increase the clarity of waterway definitions of the waters of the U.S. under the Clean Water Act has been added to the cumulative impacts analysis in Section 4.5. We note that rule was stayed on October 9, 2015 by the U.S. Court of Appeals for the Sixth Circuit and is awaiting further action.
NA	EPA	Page 4-66, Stream Miles Downstream of Mine Sites Experiencing Water Quality Improvements: It seems this section would be better suited in the Cumulative Impacts section (4.5) because any evaluation of downstream impacts should consider additional disturbances existing in the watershed.	The EIS includes assessment of downstream impacts to streams as indirect impacts of the SPR. These are discussed in section 4.2.1 of the EIS.
NA	EPA	Page 4-333, paragraph I: We recommend that cumulative impacts and alternatives analysis consider existing, baseline condition of the resources when evaluating future actions.	The cumulative impacts analysis considers the baseline condition of the resources when evaluating future actions. This paragraph has been revised to clarify this point, and additional detail describing the impacts of the No Action Alternative has been included.

CUMULATIVE IMPACTS			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
NA	EPA	Page 4-346, Assessment of Cumulative Impacts by Resource, Table 4.5-2: As in previous sections, the alternatives comparison is done in a qualitative fashion, with the result being "beneficial", " negative", or "neutral" cumulative effect. Given all the potential variables involved in determining cumulative effects, it is difficult to understand how the conclusions were drawn or what constitutes the differences between result categories.	OSMRE agrees and acknowledges in Section 4.5.1 that cumulative impacts analysis for a rulemaking of this scale is challenging. As discussed, "Beneficial or countervailing cumulative effect" means that, in combination with other actions and trends, the Alternative is expected to result in either a net increase in beneficial impacts or a net reduction in adverse impacts to the resource; "Negative cumulative effect" means that, in combination with other actions and trends, the Alternative is expected to result in a net increase in adverse effects to the resource; "Neutral cumulative effect" means that, in combination with other actions and trends, the Alternative is expected to produce little or no discernible effect on the resource; and "Indeterminate cumulative effect" means that the combined effect of the Alternative, in combination with other actions and trends, is difficult to characterize with confidence given the mix of countervailing influences. For many resources, the rule is anticipated to result in beneficial direct and indirect effects. These effects would be beneficial or countervailing to ongoing trends in affected resources, depending on the resource and site-specific factors. Socioeconomic resources are highlighted because of their potential negative cumulative effects.
OSM-2010-0021-0696	Murray Energy Corporation	Impacts of the AlternativesSection ES.8, p. ES-45"The cumulative impacts analysis recognizes that in most cases the contribution to the cumulative impacts for a given resource from implementing the Action Alternatives is difficult to discern, at a broad programmatic level across the U.S., given the context and intensity of the impacts from the other past, present and future actions. . . . For resources other than socioeconomics, the analysis concludes that the Action Alternatives (except for Alternative 9) would have a "beneficial or countervailing cumulative effect," meaning that, in combination with other actions and trends, the Alternative is expected to result in either a net increase in beneficial impacts or a net reduction in adverse impacts	The Executive Summary to the EIS provides only a brief summary of the cumulative impacts analysis. The detailed cumulative impacts analysis in section 4.5 provides a summary of the ongoing and expected future trends for each resource under the No Action Alternative as well as the Action Alternatives.

CUMULATIVE IMPACTS			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		to the resource."The conclusion that the alternatives will have a beneficial or countervailing cumulative effect in combination with other actions and trends requires clarification. OSMRE needs to specify the "other actions and trends" to which it refers, and specifically define how those actions and trends contribute to Benefits related to implementation of the Proposed SPR. OSMRE appears to be relying on future conditions outside of its control or knowledge to draw conclusions about likely Benefits or countervailing effects of the Proposed SPR.	
OSM-2010-0021-0696	Murray Energy Corporation	Impacts of the Alternatives Section ES.8, p. ES-45, first and second paragraphs below bullets Alternative 1 (No Action Alternative) should be included in this discussion, since the existing rules already have beneficial effect.	A discussion of the impacts of the No Action Alternative has been added to the Executive Summary.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.5.1, p. 4-332, bullets Not only does this cumulative impacts analysis pertain only to surface mining, or does not separate surface from underground mining, but it also uses "typical" for every subject: "typical" watershed, land cover, geology, soils, topography, air quality, etc. to establish the cumulative impacts. It should be using real data for surface mining and for underground mining, and dividing them into logical groups, by region, ecoregion, state, etc.	The EIS analysis of the SPR, including section 4.5.1, pertains both to surface and underground mining activities. OSMRE agrees that analysis at the mine level is important to understand. However, due to the broad geographic scope and timeframe for the analysis, we are unable to forecast conditions at every future mine site as part of this EIS. The 13 model mines across the seven major coal regions were developed in order to capture regional variability in terms of mining methods as well as regional context as much as was feasible.
OSM-2010-0021-0696	Murray Energy Corporation	Economic growth is the goal of most communities in the U.S., regardless of the impact on anything else. If OSMRE asserts that economic growth due to coal mining can add to the environmental stress of resources, then it should be made clear that every other type of economic growth also adds environmental stress. Coal mining should be considered a stand-alone activity, not linked to other forms of environmental concern that it cannot control. Mining does not control rural and urban development, the timber industry, agriculture, industries such sugar cane and cotton, population growth, etc. How would effects of mining be differentiated from other contributing sources?	Other actions that affect the same resources that the Proposed Action affects must be considered in an EIS. In particular, OSMRE must evaluate other past, present, and reasonably foreseeable future actions that are not related to the Proposed Action in the context of a cumulative impact analysis. In this context, OSMRE considers these other factors in section 4.5 of the EIS. These actions are not included in the direct and indirect effects of the actions.

5. Baseline

BASELINE			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
OSM-2010-0021-0048	North American Coal	Because such a large amount of time has passed since OSMRE raised the issue of additional stream protection under SMCRA, a significant amount of other new federal water quality and stream protection measures, policies and guidance have been developed and implemented, or are in the process of being implemented. These include the U.S. EPA/US Army Corps of Engineers new definition of "Waters of the United States", finalization of the U.S. EPA Multi-Sector General Permit for Coal Mining, and U.S. EPA's development of aquatic life criterion for selenium among others. OSM's DEIS fails to account for the effect of these actions that significantly mitigate OSM's perceived need for the proposed Stream Protection Rule.	A discussion and considerations of the current status of U.S. EPA's Clean Water Rule (addressing the waters of the U.S. definition) as well as U.S. EPA's Multi-Sector General Permit for Stormwater Discharges has been added to the EIS in section 4.5 (Cumulative Impacts). A discussion of the aquatic life criteria for selenium has been incorporated into the EIS in sections 4.2.1 (Water Resources) and 4.3.4 (Public Health and Safety).
OSM-2010-0018-10336	Conservation Law Center	The Clean Water Act will not act as a stopgap if a regulatory authority decides to use form as a proxy for function. The DEIS states that restoring form and function is also required under the No Action Alternative because of Clean Water Act requirements. This is mistaken. Although the regulatory text requires replacement of form and function, the Army Corps and some courts currently interpret the Clean Water Act to allow surface mining applicants to use structure as a proxy for function, despite the scientific evidence that no such link exists. (The only way that OSMRE can ensure that applicants replace stream function is to clearly state in the final rule that regulatory authorities and applicants may not use form as a proxy for function.)	OSMRE agrees with the commenter that there is some discretion on the part of regulatory authorities with respect to demonstrating restoration of intermittent and perennial streams compliant with Clean Water Act requirements. However, the analysis of the Action Alternatives finds that current stream restoration practices for intermittent and perennial streams are unlikely to change as a result of the SPR. That is, the Action Alternatives are not expected to change the standards of restoration for intermittent and perennial streams.
OSM-2010-0021-0049	Interstate Mining Compact Commission	The Federal Register states that the Proposed Rule is being based on the 1983 rule language that was in place prior to the 2008 rule- i.e., the No Action Alternative. However, the statement in the DEIS claims that there is no real difference in impacts between the 1983 rule and the 2008 rule. There is no justification to back this statement up, and it is untrue except in two states that rely on OSMRE for SMCRA regulation. If OSMRE is now stating that the 2008 rule is virtually identical to the No Action Alternative, reasoning follows that all alternatives have been evaluated against the 2008 Rule instead of the 1983 rule.	Alternative 9 would require the repromulgation of the currently vacated 2008 Stream Buffer Zone rule. This Alternative would require minimization of excess spoil generation, place limits on excess spoil fill capacity to match the anticipated amount of excess spoil to be generated, and prohibit mining activities in or within 100 feet of an intermittent or perennial stream unless the applicant demonstrates and the regulatory authority finds that avoidance is not reasonably possible. The model mines analysis indicates that the impacts of Alternative 9 would not differ significantly from those of the No Action Alternative because the

BASELINE			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
			Clean Water Act requirements and policies discussed in the Regulatory Impact Analysis for this rulemaking and the state AOC and excess spoil policies identified in Section 4.2.3.1 of this DEIS have effectively achieved implementation of this Alternative in Central Appalachia, which is the region in which the 2008 Stream Buffer Zone rule would have had its greatest impact if it had remained in effect. Therefore, if repromulgated, Alternative 9 would now have Negligible effects on socioeconomic resources evaluated in this DEIS.
OSM-2010-0021-0696	Murray Energy Corporation	OSMRE cannot definitively state that certain mining regions have more ephemeral streams than other regions, given that there are thousands of unidentified ephemeral streams (especially in the Appalachian region) and USACE has no consistent policy for determining and tracking ephemeral streams in the U.S. For example, in Tennessee, USACE has recently started mandating identification of ephemeral streams and requiring mitigation for their loss, using the USACE Regulatory Guidance Letter 05-05 (December 2005). This has resulted in the identification of hundreds of "streams" that the TN State Department of Environment and Conservation calls wet weather conveyances and which do not require mitigation.	OSMRE acknowledges that data on ephemeral stream lengths and densities across the U.S. is not available. However, the statement that the comment refers to is based on reasonable assumptions that the lack of precipitation in these regions would result in groundwater levels occurring well below the level of surface streams, thereby supporting an expectation that these regions would have a relatively greater percentage of ephemeral streams than other less arid regions.
OSM-2010-0021-0696	Murray Energy Corporation	OSMRE uses inconsistent language throughout the alternatives description, existing environment, and environmental consequences sections. OSMRE should provide greater clarity as to what it is relying upon for baseline conditions.	Language used in the alternatives description in EIS Chapter 2, affected environment in EIS Chapter 3, and environmental consequences in EIS Chapter 4 has been reviewed and edits have been made in an effort to make the language more consistent across sections.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.5.2.3, pp. 4-338 to 4-339, last paragraph "State forestry programs may promote best management practices (BMPs) that are intended to protect water resources, among other resources. For example, Tennessee's BMP guide recommends practices such as establishment of streamside buffer zones, soil stabilization through reforestation, and use of sediment control structures (Tennessee Department of Agriculture, 2003). In conjunction with the Proposed Action, these BMPs could reduce forestry impacts such as sedimentation and riparian vegetation removal."	The EIS does not dispute that agriculture and runoff from other industries is a significant contributor to water quality issues in the United States, as is recognized in section 4.5.2.3 of the FEIS. OSMRE agrees that impacts of the rule on mining activities on water quality must be considered in light of other contributing factors. However, the primary purpose of the analysis is to understand the incremental impacts of the SPR on the environment. The impact of other nonpoint source pollution is already captured

BASELINE			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		OSMRE fails to specify rules that govern forestry and agriculture with respect to BMPs. As stated in the first paragraph under the Agriculture Trends heading (DEIS 4-339), U.S. EPA's (2000) water quality report shows that agricultural nonpoint source pollution was the leading source affecting water quality in rivers and lakes. OSMRE should consider the effects on watersheds from mining relative to these and other contributing sources.	within the status of waters as they exist today, and is therefore captured within the descriptions of existing waters in the Affected Environment discussion of chapter 3.
OSM-2010-0021-0068	Earthjustice	The EIS rests on the premise that the wholesale destruction of streams by valley fills and mine-throughs is permissible under the current regulations. OSMRE is wrong. Current regulations do not allow adverse effects on streams from filling or mining through streams. In fact, the current regulations plainly and unambiguously prohibit any mining activity within 100 feet of a stream that will have an adverse effect on the environmental resources of the stream. It is unlawful and irrational to use a less-protective regulation as the baseline for analysis under NEPA.	Thank you for the comment. The DEIS uses the pre-2008 rules as the baseline for all proposed changes. See 80 FR 44447- 44450 (July 27, 2015). Under these rules the regulatory authority must find that the proposed mining activities would not cause or contribute to a violation of applicable water quality standards and would not adversely affect the quantity or quality of the water in the stream or other environmental resources of the stream. See 48 FR 30312, 30327-30328 (Jun. 30, 1983). This language does not represent an unambiguous prohibition against mining activity within 100 feet of a stream.
OSM-2010-0021-0068	Earthjustice	Further, it would be arbitrary to conclude that the current stream buffer zone rule would remain poorly enforced in the future while simultaneously assuming that new protections adopted through the Stream Protection Rule will be well enforced. Certainly, OSMRE cannot assume that the enforcement of SMCRA's minimum standards will improve without explaining what concrete steps OSMRE will take to improve enforcement.	Please refer to the discussion of rule implementation contained within the preamble to the rule.
OSM-2010-0021-0696	Murray Energy Corporation	Surface Water Overview. Section 3.5.2.3, Table 3.5-1 Table 3.5-1 highlights the estimated total stream length (intermittent and perennial) for each coal seam region. However, it is not clear what percentage of these would be within or proximate to economically viable coal reserves that could feasibly be mined in the future. Without this context, it is impossible to estimate what potential implication the "Seepage-Run Determinations" may have for any given region (Proposed SPR § 784.19 (C)(3)(D)).	Table 3.5.1 lists the intermittent and perennial stream lengths in areas where there are minable coal reserves. OSMRE estimates that 100 percent of the stream lengths shown in the table would be within or proximate to economically viable coal reserves. The Model Mines analysis employs representative models of the dominant mining methods, sizes, and overall operations in each region. Because of the unique site-specific characteristics of each mine, it makes a comprehensive, mine by mine,

BASELINE			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
			analysis impracticable. Therefore, the Model Mine analysis provides a method of analyzing representative mining scenarios to forecast potential impacts of each alternative to cost and operational trends in the industry. As part of the Model Mines analysis, OSMRE forecasts how the rule would impact the future production and proliferation of coal mines using No Action Alternative and Action Alternative scenarios. The forecasted impacts to streams, expected mine placement, and projected coal production were based on current trends from a variety of data sources, and were estimated for each region based on their overall general conditions. However, it is not possible to determine where future mines might be placed beyond what can be extrapolated from the historical data. Because there is uncertainty in future placement of mines, it was not possible to determine the potential implication the “Seepage-Run Determinations” may have for any given region.
OSM-2010-0021-0696	Murray Energy Corporation	*Section 4.5.2.1, p. 4-335, first paragraph* *EPA authorizes state environmental agencies to administer components of the CWA. For example, all states where coal mining occurs have approval to issue NPDES permits.* According to U.S. EPA's NPDES State Program information page, New Mexico does not have an approved NPDES program, although it is pending.	The language in this sentence in section 4.5.2.1 has been clarified.
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.8.2.2, p. 3-246 "Mining (including but not limited to coal mining) has been identified as a contributing factor in the past and ongoing decline of some species. For example, the U.S. FWS described a primary threat to greater sage grouse as ongoing fragmentation and loss and fragmentation of shrub steppe habitats through a variety of mechanisms related to activity that transforms the land, including agriculture, oil and gas development, mining, urbanization, and infrastructure development that includes roads and power lines that convert or bisect habitats and introduce invasive species (75 FR 13909 (March 23, 2010)." OSMRE consistently interjects impacts into the baseline	No change is required. The text referred to in the comment is describing the current status of one resource, in this case the greater sage grouse, as part of the affected environment discussion. The contributing factors to the species' current status include mining activities and thus mining is mentioned here as part of the description of the resource and part of the affected environment discussion; this is different than the analysis of how mining under each of the proposed alternatives would affect this resource, which is discussed in the environmental consequences section of chapter

BASELINE			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		description. Existing environment descriptions and environmental consequences are separate concepts. These statements often are not even related to mining but imply that mining is the cause of the impact. OSMRE should provide an accurate and objective description of the baseline environment that is free from references to or discussion of environmental impacts.	4.
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.8.3.3, pp. 3-252 to 3-253 OSMRE should clarify why algae (and numerous other taxa) are discussed. It is not clear how OSMRE intends for algae to be used in the Proposed Rule. In this section (Section 3) and Appendix B and C of the DEIS, various attributes of aquatic systems are described without explanation of the relevance to the Proposed SPR, particularly with regards to baseline monitoring or reclamation targets. Given the Proposed SPR's numerous open ended references to restoration of a stream's ecological structure and function, OSMRE should clarify whether it intends to assess and use numerous biological endpoints in biological monitoring programs to determine whether ecological structure and function are restored.	This Section describes the environment of the areas to be affected by the alternatives under consideration, as required by 40 CFR 1502.15. Limiting the discussion to only those organisms that are directly relevant to the implementation of the rule would not meet the requirements of 40 CFR 1502.15 to "describe the environment of the area(s) to be affected or created by the alternatives under consideration." Baseline data collection and monitoring requirements under the Action Alternatives would require use of a scientifically defensible bioassessment protocol based upon the measurement of an appropriate array of aquatic organisms but not necessarily all of the organisms discussed here in the affected environment section. The make-up of organisms would be determined by the state or tribal agency responsible for preparing the water quality inventory required under section 305(b) of the Clean Water Act, 33 U.S.C. 1315(b) when this agency approves the bioassessment protocol.
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.8.3.3, p. 3-253 "There are few differences between the numbers of invertebrate taxa in permanent streams versus those found in intermittent stream reaches in several northern Alabama streams (Feminella, 1996)." Feminella (1996) looked at only 6 intermittent streams (though 1 was considered rarely intermittent). Seventy-five percent of 171 taxa were present in all 3 types of intermittent streams. Feminella (1996) did not examine permanent streams. Therefore, OSMRE is drawing conclusions that are not supported by the Faminella (1996) study.	We agree that Feminella looked at only six streams, including 2 normally intermittent, 3 occasionally intermittent and 1 normally perennial. Feminellla concluded that small intermittent and permanent streams displayed generally high similarity in benthic fauna and that assemblages of normally intermittent streams do not differ greatly from those of nearby permanent streams. Difference in stream assemblages, at least in part, can reflect spatial and temporal variation in stream permanence. These conclusions provided in the Feminella study as well as those in the Stout

BASELINE			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
			and Wallace, 2003 study show little difference in the number of invertebrate taxa found in permanent streams versus those found in intermittent streams. The conclusions OSMRE has made in regards to difference between taxa in permanent versus intermittent stream reaches is supported by both the Feminella, 1996 study and the Stout and Wallace, 2003 study. No changes have been made as a result of this comment.
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.8.3.3, p. 3-253 "This suggests that there is sufficient water present in the headwaters for long-lived taxa with multi-year life cycles to complete their juvenile development prior to reaching the aerial adult stage." OSMRE should change the term "is" to "maybe." The term 'headwaters' can apply to ephemeral, intermittent, or perennial streams. A headwater perennial stream is very different from a headwater ephemeral stream. OSMRE should clarify the meaning of this statement.	We agree that the term "is" should be changed to "may be" in regards to headwaters. As the commenter stated, headwaters can apply to a variety of streams including ephemeral, intermittent and perennial streams and each has its own unique flow regime. The importance of this statement lies with maintaining existing flows to allow long-lived taxa with multi-year life cycles to complete their juvenile development, specifically maintaining the hyporheic zone to allow macroinvertebrates to survive during times of drought or low water flow. We have changed the text from "is" to "may be" (see section 3.8.3.3) to provide sufficient clarity that there will be unique situations that sufficient water may not be present during extended droughts.
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.8.3.3, p. 3-253"Studies of Appalachian headwater streams show that C. bartonii usually accounts for the majority of benthic macroinvertebrate biomass (Seller and Turner, 2004)."OSMRE is incorrect. Seiler and Turner (2004) examined nine streams in northwestern PA, and concluded that the work was not representative of "Appalachian headwater streams" throughout the Appalachian region. In fact, Lieb et al (2011) and Edwards (2014) demonstrate that crayfish and other macroinvertebrate species have changed in abundance and dominance in headwater streams over time.	Although, the conclusion that Cambarus bartonii usually accounts for the majority of benthic macroinvertebrate biomass in Appalachian headwater streams is not new and has been shown by many researchers including, but not limited to Woodall & Wallace, 1972; Huryn & Wallace, 1987, Griffith, Perry & Perry, 1994, Griffith, and Wolcott & Perry, 1996; we have decided to remove this sentence as it does not provide any additional pertinent information to this paragraph. The removal of this sentence is not a major revision and simplifies the understanding of this paragraph.
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.8.3.3, pp. 3-255 to 3-256 OSMRE selectively chose what information to analyze in the	This comment is incorrect and no change to the text is warranted. The text (see the

BASELINE			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		DEIS in order to support a predetermined resolution. OSMRE should discuss all fishes in the Appalachian region, not just those in West Virginia.	"Vertebrates" discussion of section 3.8.3.3) describes fishery resources for streams in several parts of the Appalachian Region, and does not focus exclusively on West Virginia.
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.8.3.4, p. 3-257 "The listed species include birds, fish, insects, mammals, mollusks, amphibians, reptiles, and vascular plants (see Appendix F for species names)." References to Appendix F are inadequate for identifying listed species specific to this region because the appendix is a summary for all regions collectively. OSMRE should separate the Appendix into listed species by cover type by region.	The comment is correct. A column has been added to the table in Appendix F to indicate the regions in which each species is listed as occurring. Additional information can be found within the Biological Assessment and Biological Opinion (when issued) documents available associated with the Stream Protection Rule.
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.8.3.4, p. 3-258, Figure 3.8-2 Moreover, the discussion of species in the DEIS should include the species represented in this figure, or at a minimum, each group (Order) of taxa listed. OSMRE should provide transparency with respect to its sources of information.	Additional information on listed species and listed species impacts can be found within the Biological Assessment and Biological Opinion (when issued) documents associated with the Stream Protection Rule.
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.8.4.2, p. 3-263 "The Colorado Plateau coal region encompasses coal-bearing areas of Arizona, Colorado, New Mexico, and Utah. The text below summarizes aspects of terrestrial resources in areas of the region as classified under the USDA-USFS Terrestrial Ecological Unit designation (see also Figure 3.8-3) and adapted from Bailey (1995), McNab and Avers (1994), Cleland et al (1997), and McNab et al. (2007). Table 3.8-3 lists the aerial extent of each unit within the Appalachian Coal Basin." OSMRE should change "Appalachian Coal Basin" to "Colorado Plateau coal region."	We have changed the term in response to this comment. See Section 3.8.4.2
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.8.9.4, pp. 3-319 to 3-320"As shown in Figure 3.8-13 there are 13 federally listed and proposed listed species in the Western Interior region; two birds, three fish, three mussels, two plants, two mammals, and one insect."OSMRE's figures summarizing the counts of federally listed species are misleading when the scale of each figure is different by region. This figure gives the reader a visual impression that there are many species, because the histogram scale tops out at 3. For the Appalachian Basin, the scale is 50; for the Colorado Plateau the scale is 20. OSMRE should use a more consistent scale in these figures.	No change has been made in response to this comment, although the histograms have been updated to reflect the final species list (see Appendix F). Consistency in vertical scale would be critical if the data for each region were shown side by side instead of on separate pages as they are currently. The histograms as depicted give the reader a quick perception of the relative make-up of listed species within a region by taxonomic group only so that the reader can see which taxonomic groups are of

BASELINE			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
			higher relative importance in any particular region. Comparing the number of listed species from one region to another would not be informative since the regions vary greatly in the area they encompass. Calculating the number of species per area to account for this difference would provide a calculation of the density of listed species per area (and not the density of individuals per area) and so would not be additionally informative.
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.9.1, p. 3-320 "Wetlands can be described as "the halfway world between terrestrial and aquatic ecosystems, exhibiting some of the characteristics of each system" (Mitsch and Gosselink, 2007). The Clean Water Act (CWA) defines a wetland as "those areas that are inundated or saturated by surface or groundwater at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions" (33 CFR Part 328). Commonly used terms for wetlands include swamp, marsh, bog, wet meadow, fen, pocosin, pothole, and vernal pool" OSMRE should identify the criteria used to define a wetland. For example, USAGE's (1987) identification manual and subsequent regional supplements are the commonly used references for wetland identification and delineation. Wetlands have the following three characteristics: vegetation, hydric soil, and hydrology.	No change is necessary. This text within chapter 3 is providing a functional definition of wetlands to introduce the reader to the concept of wetlands, including those that would not meet the criteria for CWA jurisdiction. Appendix C references the USACE 1987 manual and the definition of wetlands found in the manual.
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.9.2, p. 3-321 "Freshwater wetlands loss is mainly caused by urban and rural development (Dahl, 2006)." Although Dahl's 2006 publication does not state the percentage of freshwater wetlands loss, he does state in a 2011 publication that 62,300 acres of freshwater wetlands were lost between 2004 and 2009. Since most of this loss is caused by development, with no information provided regarding the loss of wetlands due to coal mining, OSMRE should explain the purpose for including this section.	NEPA requires a description of the environment of the areas to be affected or created by the alternatives under consideration. 40 CFR 1502.15. The alternatives under consideration would affect wetlands; the purpose of this section therefore is to provide a baseline description of wetlands including the current status of these resources and the contributing factors to the existing status. The impacts of mining under the alternatives being considered are addressed in Chapter 4 within the Environmental consequences section, as required by 40 CFR 1502.16.
OSM-2010-0021-0696	Murray Energy	Section 3.11.1, p. 3-348"In many of the coal-producing	No change is necessary in response to this

BASELINE			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
	Corporation	regions mining has resulted in altered visual landscapes. Substantial areas now have non-native or fragmented vegetation with modified landforms; exposed acidic soils and spoil piles are visible and are distinct from natural land contours; and mining related infrastructure such as buildings, rail spurs, and road systems are present in areas that otherwise are remote and have few structures. Coal mines dominate foreground and middle ground views in the affected view sheds; background views generally depend on the status of reclamation activities and the perspective from a particular observation point."Paragraph two is subjective and highly critical of mining. It makes no effort to incorporate reclamation advances.	commentThe quoted paragraph lists commonly visible features that remain after coal mining has occurred but expresses no opinion on whether or not these features are visibly appealing. No subjective or critical statements are made.
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.11.2.6, p. 3-352 "While there is currently little mining activity ongoing in the region, the coal beds of this region are located in areas with high scenic value. Within the state of Washington coal beds exist in the Columbia Plateau, between the Cascade Range to the west and the Rocky Mountains in Idaho, to the east." OSMRE should clarify whether all coal beds are located in areas with high scenic value. OSMRE also should clarify what is meant by scenic value and disturbances of scenic value.	The text is clear and is speaking in general terms that the Northwest Region is highly scenic including in areas that coincide with coal resources.
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.11.2.7, p. 3-352 "Somewhat similar to the Illinois Basin coal-producing region, this region has a landscape that is primarily flat, with open crop and grass lands. The Oklahoma and Arkansas portions of this region have somewhat greater topographic relief, more extensive forest land cover, and may include greater visual resources. While historically this area was a large coal producer, coal mining has decreased significantly in the region. Most coal mining activities subject to SMCRA involve reclamation activities at inactive coal mining properties and the few scattered active mines remaining in this region." OSMRE should provide information on how current mining activities in this region are affecting visual resources.	Impacts to visual resources from the No Action Alternative are discussed in Sections 4.3.1.1 in the context of the impacts on property values and in 4.3.3.1 in the context of recreation. Effects are also captured within the discussion of cumulative impacts in 4.5.1.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.1.1.3, p. 4-35, Figure 4.1-4 Four of the major producers listed on the graph have filed for bankruptcy protection, with one, James River, filing Chapter 7. Arch is reportedly on the verge of Chapter 11 if economics do not soon change for the better.	Thank you for your comment. The graphic referred to has been removed in the FEIS and replaced with updated information. The FEIS now recognizes that, during the difficult periods in 2015 and 2016, a significant portion of the industry filed for bankruptcy. It further

BASELINE			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
			recognizes that all but one of the larger companies in bankruptcy has emerged from bankruptcy. Two of the five major supply regions (i.e., Central Appalachia and the Powder River Basin) have been affected the most as a result of declining demand.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.1.1, p. 4-47"[T]he regulatory authority may authorize mining activities in or adjacent to perennial or intermittent streams only when the permit applicant has successfully demonstrated that the "activities will not cause or otherwise contribute to the violation of State or Federal water quality standards, and will not adversely affect the water quantity or other environmental resources of the stream. ""Based on the relevant definitions, placing fill material in a stream would "cause or contribute to the violation of state or federal water quality standards." This would violate many state narrative standards prohibiting addition of materials to streams that result in visible solids, scum, or formation of bottom solids. Such narrative standards also typically include prohibiting depositing waste materials in such a manner that allows entry into streams.	No change is required because the text is quoting straight from existing regulations. Thank you for your comment.
OSM-2015-0002-0008	Natural Resource Partners LP	The Proposed Rule and accompanying analyses do not adequately address the address the scope and significance of the impacts on the human environment given the recent substantial rule changes by the U.S. EPA's carbon dioxide emission rules for new and existing power plants.	The Final RIA and FEIS for the SPR consider a number of recent U.S. EPA regulations as part of the baseline for the analysis. These are articulated in Chapter 3 and Appendix F of the RIA. These are also discussed in the cumulative impact analysis in section 4.5 of the FEIS. The Final RIA and FEIS baselines have been updated since the DEIS was released to the public.
OSM-2010-0021-0696	Murray Energy Corporation	Alternative 2 Section 2.4.2, p. 2-12, second paragraph "Alternative 2 would change water monitoring and reporting requirements before and during mining operations and during reclamation. The regulatory authority would be required to coordinate with Clean Water Act implementing agencies to harmonize baseline data collection and monitoring requirements to the extent consistent with each agency's statutory authority and responsibilities." OSMRE fails to indicate in the different alternatives what exactly would need to be harmonized between the Proposed	No change is required. The text is referring in a general way to the fact that implementing the rule revisions under the Action Alternatives would not overlap or supersede the work of other agencies in regulating water quality. Instead, if adopted, it would harmonize implementation of both SMCRA and the Clean Water Act by encouraging coordination of permitting and enforcement activities and by relying upon existing Clean Water Act water quality standards, effluent limitations, and

BASELINE			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		SPR and CWA, including which authority would be dominant and how opposing requirements would be resolved. The need for harmonization is not evaluated in the DEIS or RIA.	designated uses of surface waters to the extent possible. However, the scope of the Clean Water Act is not as broad as SMCRA with respect to protection of the hydrologic balance and prevention of material damage to the hydrologic balance outside the permit area, both of which are requirements of SMCRA. Nothing in the Clean Water Act regulates groundwater and, with respect to surface waters, not all streams have designated uses. Clean Water Act water quality standards and effluent limitations do not exist for all parameters that could adversely impact the hydrologic balance. The proposed alternatives would fill these regulatory gaps.
OSM-2010-0021-0066	NMA	The SPR states and therefore the DEIS implies: "To the extent possible using the best technology currently available, the proposed operation has been designed to minimize disturbances and adverse impacts on fish, wildlife, and related environmental values, and to achieve enhancement of those resources where practicable, as required under the SPR." The "practicable" standard is cited in many proposed DEIS and SPR sections with no definition or guidance as to what this term means. The responsibility is on the applicant to hit what could be a moving compliance target, which is under the control of the regulatory authority (or U.S. FWS) with no mutual understanding of what is meant by this term.	No change required. The term "practicable" is part of our existing regulations and occurs first in the definition of "Best technology currently available". 30 CFR 701.5. Per the definition the existing definition, "Best technology currently available" means "equipment, devices, systems, methods, or techniques which will (a) prevent, to the extent possible, additional contributions of suspended solids to stream flow or runoff outside the permit area, but in no event result incontributions of suspended solids in excess of requirements set by applicable State or Federal laws; and (b) minimize, to the extent possible, disturbances and adverse impacts on fish, wildlife and related environmental values, and achieve enhancement of those resources where practicable. …" 30 CFR 701.5. Therefore this term is not newly proposed within the SPR but is rather already a familiar concept implemented through existing regulations.
OSM-2010-0021-0066	NMA	In addition, if the U.S. FWS field office does not concur with the Regulatory Authority's decision and the Regulatory Authority and the U.S. FWS field office are subsequently unable to conclude an agreement at that level, the SPR allows either the Regulatory Authority or the U.S. FWS to elevate the issue through the chain of command of the Regulatory Authority, the U.S. FWS, and OSMRE for	Thank you for the comment. In response to similar comments on the rule we have made clarifying changes in the final rule, i.e. the Preferred Alternative. These changes clarify what the applicant must demonstrate to the regulatory authority regarding ESA compliance for a proposed permit; these demonstrations are

BASELINE			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		resolution. It also provides that the Regulatory Authority may not approve the permit application until all issues are resolved in accordance with this process and the Regulatory Authority receives written documentation from the U.S. FWS that all issues have been resolved. This is beyond the standard and regulatory process of ESA section 7 – jeopardy determination. This essentially provides the U.S. FWS with veto authority whenever the service disapproves of resource findings or finds a protection and enhancement plan to have the potential to harm species under the proposed SPR. Notably, this threshold is less than that which is required under Section 7.a.2 of the ESA, which requires jeopardy to species and/or a potential "take."	consistent with existing ESA regulations and provide no additional authority to the Services. See section 773.15(j) of the final rule and the discussion in section IV.J. of the preamble to the final rule.
OSM-2010-0021-0066	NMA	Several alternatives (including the Preferred Alternative) would allow the U.S. FWS torequest an opportunity to review the fish and wildlife protection and enhancement planssubmitted as part of other permit applications even when the resource information inthose applications does not include species listed as threatened or endangered underthe Endangered Species Act, critical habitat designated under that law, or speciesproposed for listing as threatened or endangered under that law. [...] This is beyond the purview and ESA responsibilities of the U.S. FWS. Under Section 7,U.S. FWS is required to prepare an assessment (biological opinion) of impacts to listedand proposed species. Requesting review of the protection and enhancement plan forspecies not listed or proposed within a 10-day timeframe is unreasonable andburdensome to the Regulatory Authority (or applicant) in terms of additional time andmonetary costs to provide the information.	In response to similar comments on the proposed rule we have made additional clarifications in the final rule and the preamble to that rule. Please see the preamble, Section IV.J." *We Should Remove the Provisions that Grant "Veto Power" Over SMCRA Permits to the U.S. Fish and Wildlife Service."* for a complete discussion of changes that were made in response to these and similar concerns.
OSM-2010-0021-0696	Murray Energy Corporation	Federally Protected and Regulated Species Section 3.8.2.2, p. 3-245 "The ESA makes it unlawful to "take" (defined at Section 3(19) of the ESA as "to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or to attempt to engage in any such conduct") federally listed threatened or endangered species without a permit on federal lands." OSMRE should remove the words "on federal lands." A permit is needed for take on any land. Section 9(a)(l) of the ESA also prohibits any person subject to the jurisdiction of	The reference to federal lands was removed. See section 3.8.2.2.

BASELINE			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		the U.S. from taking any listed species, regardless of the existence of a federal nexus.	
OSM-2010-0021-0696	Murray Energy Corporation	Alternative2 Section 2.4.2, p. 2-12, second paragraph OSMRE appears to reconcile the continuing scientific and engineering debate regarding the new interpretation of portions of the CWA with respect to "waters of the United States" and definitions of "adjacent areas," "hydrologic balance," "material damage," and "ecological function." It is unclear what documents OSMRE reviewed, other than the U.S. EPA SAB report on waterways cited in the Proposed SPR with respect to the structure and function of waterways.	For studies cited in the proposed SPR see 80 FR 44436–44698 (July 27, 2015).
OSM-2010-0021-0066	NMA	The Preferred Alternative and Alternative 2 defines streams employing the definition of "waters of the U.S." (WOTUS) and interpreted under 40 C.F.R. section 230.3(s) and CWA section 404(b)(1). This definition is currently in litigation and subject to change. Moreover, some aspects of the WOTUS definition can be applied only on a case-by-case basis. Under SMCRA section 702(a), OSMRE may not amend any provisions of the CWA. Thus, any variations to the definition introduced by OSMRE in the alternatives are prohibited by SMCRA. Further, because the revised definition of WOTUS is currently subject to challenge and has been stayed nationwide by the U.S. Court of Appeals for the Sixth Circuit, OSMRE should avoid finalizing any rule that relies on that definition until that litigation is resolved.	Thank you for the comment. In response to comments on the rule itself we have replaced the term "waters of the United States" (WOTUS) with "perennial, intermittent, and ephemeral streams" or its equivalent in text that pertains only to streams. The change is nonsubstantive, but it clarifies the scope of the rule and avoids the controversy surrounding the definition of WOTUS.
OSM-2010-0021-0066	NMA	However, Alternative 7 would require coordination with the CWA authority on defining stream flow condition, and requires that the permit applicant and the Regulatory Authority seek input from the USEPA (as CWA authority) for all new applications, and incorporate, where applicable, all the USEPA's potential to impact WOTUS. Importantly, the definition of WOTUS has gone through many modifications since it was first defined in 1986 and continues to be in flux. At the present time, the definition of WOTUS is in litigation. The requirement of the applicant and the regulatory agency to meet the requirements of the CWA is acknowledged, but Alternative 7 introduces significant uncertainty as a result of its reliance on a rule still subject to challenge that is currently stayed. Therefore, the definition of stream type for Alternative 7 is flawed.	Thank you for the comment. We replaced the term "waters of the United States" (WOTUS) with "perennial, intermittent, and ephemeral streams" or its equivalent in text that pertains only to streams. The change is nonsubstantive, but it clarifies the scope of the rule and avoids the controversy surrounding the definition of WOTUS.
OSM-2010-0021-0007	Virginia Department of Historic Resources	"As the State Historic Preservation Office in Virginia, DHR agrees with your assessment that all Alternatives are likely	The text in Section 3.13 has been updated and reflects the current status of the federally

BASELINE			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		to have Negligible impacts on Archaeology and Cultural Resources (ES 41 paragraph 6; 4.3.5). We strongly recommend revision of 3.13 Archaeology, Paleontology and Cultural Resources, page 3-376, paragraph, Virginia. It is no longer the case that there are currently no federally recognized tribes in Virginia today and very little is known about the tribes at the time of contact. Much is known about the tribes at the time of contact from both documentary and archaeological evidence."	recognized tribe in Virginia.
NA	EPA	Page 3-321, Section 3.9.2 Wetlands Status and Trends, second paragraph, first sentence; Suggest re-phrasing or deleting the sentence, "Despite regulations and a positive trend of wetland acreage, wetlands are lost in the U.S. at an estimated rate of 290,000 acres per year (Dahl, 2006)." This sentence appears contradictory and, at a minimum, is confusing.	The text in Section 3.9 has been clarified through replacement of the word "acreage" with protection. The sentence is no longer contradictory.

6. Benefits

BENEFITS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.3.2.5, p. 4-248, first paragraph OSMRE provides no evidence from the scientific literature to substantiate the claim that additional metrics collected as part of the baseline assessment will indirectly benefit land use, utilities, infrastructure, visual resources, or noise resources.	The section of the FEIS cited by the commenter states that the Action Alternatives (excluding Alternative 9) standardize the sampling protocol and increase the assessment and monitoring activities for baseline data collection and analysis, as described in Chapter 2. These changes are not expected to directly affect land use activities but may lead to indirect effects on land uses to the extent that they promote improved water quality in the region. Additional explanation for the impacts of baseline data collection on water quality are described in section 4.2.1.
OSM-2010-0021-0696	Murray Energy Corporation	*Section 4.5.3.4, pp. 4-357 to 4-358* Reduction of fugitive methane emissions from coal extraction is to be accomplished by a reduction in coal	The FEIS appropriately evaluates changes in GHG emissions as a consequence of implementing the Action Alternatives. As

BENEFITS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		production from underground coal mines as a result of the implementation of the proposed Stream Protection Rule. OSMRE should not be directing a reduction in coal production in order to reduce fugitive methane emissions from coal extraction.	directed by CEQ NEPA guidance, the FEIS evaluates the effects of the rule on GHG emissions regardless of whether the impact is direct or indirect. In this case, the FEIS finds that the rule will result in an overall reduction in GHG emissions, considering both positive and negative effects on CO_2 emissions from the electric power sector, as well as CH_4 emissions from the field production of coal and natural gas. The purpose of the Action Alternatives evaluated in the FEIS is not to reduce coal production or to reduce GHG emissions (including fugitive methane emissions).
OSM-2010-0021-0696	Murray Energy Corporation	Results of Quantitative Analysis of Surface Water Impacts Section 4.2.1.4, p. 4-71, first bullet "Shank (2010) and Shank and Gebrelibanos (2013) use GIS analysis to compile data on refuse fill in West Virginia between 1984 and 2012, and estimate linear stream loss due to fill construction over time. The more recent study estimates that 766 miles of perennial and intermittent streams were filled during the study period (1984 to 2012, which equates to 28 miles per year on average). It also shows a marked decrease infill construction starting in approximately 2003. In 2012, stream miles filled decreased to approximately 18 miles in West Virginia for that year." Two of the studies cited, Shank (2010) and Shank and Gebrelibanos (2013), determine that annual "stream" mile fill construction has decreased over time: twenty-eight miles per year from 1984 to 2012 and 18 miles per year in 2012. The vast majority of "miles" referenced are ephemeral and the highest reaches of intermittent channels. Regardless, under the No Action Alternative, fewer stream miles are being filled.	The text cited by the commenter appears in the EIS in order to demonstrate the changes that have been occurring in terms of the number of streams filled over time. OSMRE disagrees that this data necessarily shows that fewer stream miles are being filled under the No Action Alternative since these studies provide a snapshot only of a limited timeframe in a lilmited area.
OSM-2015-0002-0060	Society for Mining, Metallurgy & Exploration	Absent a science-based rationale, the choice of a 100 foot wide minimum may either be too small or too large. Riparian buffers based on a fixed-width that are not based on the hydrological, ecological and biological relationships of riparian areas may not reflect the extent of the riparian area.	OSMRE received similar comments on the proposed rule and has made clarifications and changes in the final rule in response to these comments. For example commenters voiced concern that proposed section 780.16(d)(1)(v), which is now final section 780.16(d)(2)(v), was too inflexible in requiring that, if an enhancement measure involved creating a vegetative corridor for a stream that previously

BENEFITS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
			lacked such a buffer, the buffer zone had to be at least 100 feet wide. We agree with this concern and have modified this paragraph to provide additional flexibility. The regulation now states a preference, but not a requirement, for a minimum 100-foot corridor for such enhancement measures. For clarity, we have also revised this requirement to describe the enhancement as the creation of a corridor where there is no such corridor before mining but where a vegetative corridor typically would exist under natural conditions. As to this requirement potentially providing too narrow of a corridor in some instances, OSMRE cannot disagree. Several commenters on the proposed rule alleged that the proposed 100-foot minimum width for the corridor as proposed in paragraph (d)(1) was arbitrary. Some of these commenters suggested that the regulatory authority should establish the width of the corridor on a site-by-site basis. Upon review of these comments, we are retaining the requirement for a general rule establishing a 100-foot wide streamside vegetative corridor on each side of perennial and intermittent streams, subject to certain narrowly-tailored exceptions, because this strikes the necessary balance between environmental protection and the Nation's need for coal as an essential source of energy. In the preamble to the proposed rule at Part IV and proposed section 816.57(a), we explained that this distance is consistent with our history of requiring a minimum, nationwide, 100-foot corridor width on either side of a stream. Contrary to the assertions by some commenters, this requirement has never been considered merely a "best management practice." Furthermore, as discussed in the preamble to the proposed rule, this width is supported by science (see 80 FR 44436, 44494 and 44552 (Jul. 27, 2015).
OSM-2010-0021-0066	NMA	The DEIS did not provide sufficient technical and engineering information or clarity to allow the development	Section 4.1.2 of the EIS describes that model mines approach to understanding coal industry

BENEFITS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		of the initial set of environmental conditions to provide focus for the subsequent evaluation of impacts for the different EIS alternatives. The DEIS did not involve a study design that identified valued ecosystem components and the most appropriate surrogate components for which useful predictions might be possible to evaluate impacts and changed conditions. The extent to which predicted changes are expected to influence project decisions should have been explicit in the DEIS, and they were not.	impacts. In particular, coal mine engineers developed model mines for each coal region and mine type based on conditions at existing mines as described in mine permits. This includes referencing information on locations, sizes, mining methods, topography, geology, and stream characteristics to establish a realistic physical setting for each model mine under the No Action Alternative. Specifically, surface topography from the USGS Seamless Server, GIS analysis, and AutoCAD software were used to develop contours, delineate watersheds and streams, and insert coal seams. Based upon the geology, topography, and mine size, a mineral removal boundary was created for each model mine. The engineers then re-engineered each of the model mines to comply with the Action Alternatives (e.g., in terms of changes stream fill and reclamation practices). The technical detail of the engineering analysis is provided in Appendix B of the RIA.
OSM-2010-0021-0066	NMA	The DEIS did not identify a statistical definition of natural variation that could be applied to examine the degree and permanence of environmental change and account for the resilience inherent in different ecoregions in the US where mining occurs. The DEIS did not consider the long-term potential of the different ecoregions in the US (or components thereof) to recover from predicted impacts or adapt to the changed conditions, but rather relied on the initial predicted outcome of the mining activity as the basis for drawing conclusions.	Without additional disturbance, impacts of coal mining generally attenuate over time. The DEIS does not claim to be a statistical analysis. However, cited scientific literature provides evidence that historic mining activities have led to persistent impacts to some natural resources. The EIS Chapter 4 recognizes uncertainties in this data as well as many other aspects of the analysis. This is particularly apparent in section 4.2.1, Water Resources.
OSM-2010-0021-0066	NMA	Regarding the persistence of contaminants released by surface mining, Hopkins et al. (2013) sampled older mines that were mined under older rules and had been reclaimed. That work does not demonstrate persistence of contaminants from mining completed under the existing rule.	Hopkins et al. (2013) investigated reclamation projects from less than two years old to more than 25 years in age based on permit dates. The majority of the reclamation sites studied were more than ten years old. Given that some of this study's conclusions may be drawn from mining and reclamation practices that pre-date current regulations, this citation has been removed from the sentence stating that contaminants released by surface mining persist for decades in Chapter 4.3.4.1.

BENEFITS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
OSM-2010-0021-0055	Rocky Mountain Elk Foundation	While the EIS calls primarily for native species to be used in future reclamation projects, we are pleased that there is an exception for non-native species allowance where necessary to achieve approved postmining land use if actually implemented prior to final bond release. We encourage the use of white clover, crimson clover, red top clover, and vetch, as well as sweet clover and some orchard grass to provide much needed forage and cover for many wildlife species. These are all non-native species that are not invasive, are effective at site stabilization, provide cool season forage, and are not persistent in the long-term. They allow establishment of native plants through natural colonization.	As discussed in the preamble to the final rule several commenters stated that non-native annual crops can be used to supplement natural food sources for wildlife. We acknowledge that this is true. However, we do not agree that the use of non-native species is necessary to successfully reclaim the site to the "fish and wildlife habitat" land use category. This land use category is defined within section 701.5 as land that is "dedicated wholly or partially to the production, protection, or management of species of fish or wildlife." This definition does not allow for a focus on game species to the detriment of other species, and there are no other aspects of this land use category that would necessitate the use of non-native plant species. Therefore, an exception for the use of non-natives for this land use category is not warranted.
OSM-2010-0021-0056	Utah Mining Association	OSMRE has failed to adopt a scientifically rational approach to the current understanding of ecology across the many different eco-regions in the U.S. where mining occurs.	Please refer to Chapter 3.8 for a characterization of the ecological setting of each coal mining region defined in the EIS. In this section, OSMRE describes the ecological provinces, terrestrial resources, and aquatic resources for each region. As is the focus of the SPR, particular attention is given to aquatic resources. Chapter 4 describes the impacts of mining related contaminants and disturbances to these resources. The analyses in Chapter 4 are based on modeled mines reflecting variation in mine site characteristics in each coal region, for example with respect to differing stream densities and forested land cover pre-mining.
OSM-2010-0021-0068	Earthjustice	Although OSMRE's choice between alternatives will have significant consequences for greenhouse gas pollution through methane emissions and coal combustion, OSMRE failed to analyze the greenhouse gas pollution consequences of the alternatives or disclose that pollution's social, economic, and ecological impacts	Please see Section 4.2.4 of the EIS and Section 7.3 of the RIA for a discussion of air quality and climate change related to overall changes in coal production and combustion. These sections estimate effects of the Final Rule on greenhouse gas emissions and provides monetized benefits of the Action Alternatives in terms of reducing worldwide climate-related damages.
OSM-2010-0021-0068	Earthjustice	The requirement to analyze the social cost of carbon is	Thank you for your comment. In response, an

BENEFITS			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		supported by the general requirements of NEPA, specifically supported in federal case law, and by Executive Order 13514. For all of these reasons, OSMRE must use the social cost of carbon as a way of disclosing the scope and nature of climate pollution impacts—including, but not limited to, the increase in climate pollution from coal combustion—on the human environment.	analysis of the potential impacts of the SPR on greenhouse gas emissions and the associated social costs of carbon is now included in Chapter 7 of the Final RIA and Chapter 4 of the FEIS.
OSM-2010-0021-0068	Earthjustice	Further, where that pollution is methane, OSMRE should use multipliers that reflect the latest science concerning the short- and long-term impacts of methane pollution	Please refer to section 4.2.4 of the FEIS, as well as Section 7.3 of the Final RIA, for details related to the updated quantification the benefits of reductions in GHG emissions. OSMRE applied the best available information from the 2016 EPA Greenhouse Gas Inventory and the 2016 Interagency Working Group on the Social Cost of Greenhouse Gases in evaluating impacts of the Action Alternatives on CO_2 and CH_4 emissions.
OSM-2010-0021-0068	Earthjustice	The significant threat posed by climate change should inform OSMRE's choice between alternatives, which will have a significant impact on total U.S. coal production and consumption for the foreseeable future. Alternatives that result in higher supplies of coal over the next few decades will contribute to lower coal prices and higher coal consumption, which in turn will feed our dependence on fossil fuels and add to climate pollution for decades to come.	Climate change impacts, as discussed in the EIS, have informed OSMRE's selection of the Preferred Alternative. Section 4.2.4 of the EIS discusses the potential implications of rule Alternatives on air quality, greenhouse gas emissions, and climate change. Importantly, none of the Action Alternatives explicitly targets air quality or climate change. Regardless, implementation of the elements of the Action Alternatives may have both beneficial and adverse effects on air quality, greenhouse gas emissions, and climate change. On the beneficial side, the Alternatives reduce carbon emissions from coal combustion, and increase carbon sequestration potential due to reforestation and riparian corridor requirements of Alternatives (except for Alternative 9). However, the Alternatives may also increase methane emissions from natural gas, and increase the use of equipment and vehicles to haul materials and therefore increase other emissions from these sources. Please also refer to Section 7.3 of the RIA for more information related to analysis of climate change impacts of the Final Rule.

OSM-2010-0021-0049	Interstate Mining Compact Commission	Revegetation, Soil Management, and Reforestation 4.2.3.2, p. 4-137 "These alternatives would enhance fish, wildlife, and related environmental values and ensure that the reclaimed site can support the uses it was capable of supporting before any mining, including the vegetation that it would support in the absence of human influence. These alternatives would restore previously forested areas to a native forest ecosystem as quickly as possible, except where doing so would conflict with the approved postmining land use and that use is implemented before the end of the revegetation responsibility period."The requirement for native species and reforestation will actually diminish the postmining habitat quality for several wildlife species, especially species that are valued for hunting and wildlife viewing. These include white-tailed deer, Wild turkeys, and elk. Decisions regarding habitat restoration and reclamation have to be based upon the objective of the landowner and the landscape habitat matrix that surrounds the mine site. To maximize habitat for wildlife on a contour mine in Central Appalachia that might be situated in a landscape that is 99% forested already, the best reclamation option for wildlife habitat might be planting no trees. A mine site in the Illinois Basin that is surrounded by a landscape dominated by farmland might call for 100% reforestation of the site for the very same species. This is an example of where OSMRE treats "wildlife" as if all species had the same habitat requirements and preferences. OSMRE appears to think that all wildlife species thrive only in closed canopy, continuous forests. That simply is not true.	OSMRE is aware that species have varying habitat requirements and that the promotion of any one type of habitat in a given timeframe may negatively impact species that prefer other habitats. These alternatives would require the selection and arrangement of plant species to maximize the Benefits to fish and wildlife based on their proven nutritional value for fish or wildlife, their value as cover for fish or wildlife, their ability to support and enhance fish or wildlife habitat after the release of performance bonds, and their ability to sustain natural succession by allowing the establishment and spread of plant species across ecological gradients. These requirements recognize and incorporate varying species habitat requirements both temporally and spatially.
OSM-2010-0021-0049	Interstate Mining Compact Commission	Stream Miles Downstream of Mine Sites Experiencing Water Quality Improvements 4.2.1.3, p. 4-66 and 4-67 OSMRE relies on a single study (Petty, 2010) to apply an average distance of 6.2 miles for the length of downstream impact	Please refer to Master Response on Water Quality Benefits regarding the calculation of downstream water quality improvements in each region.

BENEFITS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		from a mine site. Despite its limitations, this 6.2 mile number is used for all regions despite an admitted difference in average gradients among the regions.	
OSM-2010-0021-0049	Interstate Mining Compact Commission	Model Mine Analysis - Model Mine Assumptions 4.2.1.3, p. 4-69 "While data are not available to determine whether the Action Alternatives would reduce the number of downstream miles adversely affected by mining, implementing the Action Alternatives (excluding Alternative 9) would at least reduce the level of adverse effect within the 6.2-mile downstream areas." The statement that data is not available calls into question the validity of utilizing the model mine analysis to determine environmental impacts. It is not best available science to draw conclusions based on a model that cannot be substantiated with data. The 6.2 mile figure used throughout the model is particularly inappropriate for western ephemeral and intermittent streams that often are not connected to any downstream surface flows.	The limitation in available studies or data evaluating the impact of mining on water quality downstream of mine sites is not a limitation of the model mine methods. The model mine analysis relies on permit and other information on existing mines to determine typical mine site characteristics in each region across the No Action Alternative and Action Alternatives. The calculation of downstream water quality impacts is a distinct analysis that relies on information on the average number of streams that typically cross mine sites in each region (based on GIS analysis of existing mine sites), as well as information regarding how far downstream water quality impacts persist (relying on the 6.2 mile estimate from Petty (2010)). In addition, data describing how far downstream water quality impairments persist are scarce. OSMRE relied on the best available science from the Petty (2010) study. The number of relevant variables and the high uncertainty involved with knowing the conditions in which any particular mine would be located in the future, prevents OSMRE from developing a precise measurement of the potential downstream impacts of mining under the No Action Alternative or under the Alternatives. The analysis therefore estimates the benefits of the rule using the 6.2-mile downstream distance as an indicator and planning tool to allow comparison between alternatives. In specific response to the concerns raised in this comment, the commenter notes that the 6.2 mile result from this study is inappropriate for use in western ephemeral and intermittent streams. First, as described in Section 4.2.1 of

BENEFITS			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
			the EIS, the analysis did not apply this number to ephemeral streams to estimate downstream water quality improvements, limiting its use to intermittent and perennial streams. Second, given the lesser stream density of the western regions, the findings of the analysis are consistent with this comment in that the estimated downstream water quality improvements are limited. For example, Table 4.2.1-9 of the EIS highlights average annual water quality improvements of 16 miles for Northern Rocky Mountains area mines under Alternative 8 as compared with 104 miles for Central Appalachian contour mines.
OSM-2010-0021-0049	Interstate Mining Compact Commission	The model mine analysis attempts to demonstrate how the alternatives will impact the streams within a mining permit; however the results presented indicate that there are no real Benefits to streams in most of the coal regions under any of the alternatives with the exception of Central Appalachia surface mines. Central Appalachia is the region where fill areas are predominantly used to dispose of excess spoil material. It is disingenuous of OSMRE to assume that implementation of the proposed rule will have no differing effects on streams within any of the other coal producing regions.	The analysis does not assume that implementation of the proposed rule will have no differing effects on streams in coal producing region outside of Central Appalachia. In fact, Table 4.2.1-9 identifies that the benefits of the rule in terms of reductions in stream fills occur only in Appalachia. Analysis of other benefit categories, however are even greater in other regions. For example, ephemeral stream restoration benefits are concentrated in the Illinois Basin and Gulf Coast Regions (Table 4.2.1-11). OSMRE considers the relative magnitude of all benefit categories described in the analysis across the various coal regions, taking into account the differences in coal region characteristics.
OSM-2010-0021-0070	Luminant Mining Company LLC	Further, while the agency anticipates that the Proposed Rule would generate extensive Benefits in Appalachia and, to a lesser extent, the Illinois Basin, these Benefits do not flow to Texas, which is included as part of the Gulf Coast region in the DEIS. Even under the DEIS's wildly optimistic methodology, the Proposed Rule is expected to yield only moderate Benefits in the Gulf Coast Region with respect to water resources and biological resources. Moreover, almost no Benefits are expected with respect to air quality,	The commenter is correct in that SPR is anticipated to generate a greater degree of benefit to water and biological resources in Appalachia and, to a lesser extent, the Illinois Basin, relative to the other coal mining regions. These benefits stem from a combination of factors, including a large volume of ongoing and forecast coal production, a high density of forests and streams that are affected by this

BENEFITS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		greenhouse gas emissions, and climate change; topography, geology, and soils; land use, utilities, infrastructure, visual resources, and noise; public health and safety; archaeology, paleontology, and cultural resources; and recreation.	mining activity, and rule elements that are designed to reduce these impacts. The Gulf Coast Region produces significantly less coal than either Appalachia or the Illinois Basin (Gulf Coast Region annual production is forecast to produce 45 tons per year compared to 214 tons per year in Appalachia and 151 tons in Illinois Basin).
OSM-2010-0021-0060	Ohio Department of Natural Resources	Table 4.2.1-5 "Methods for Quantification of Benefits to Water Resources" on pages 4-64and 4-65, relies heavily on a "typical mine" and "average" values in its calculations. While the techniques may be the best available to provide a generalized picture, they would appear to introduce a range of uncertainty that is potentially significant, or at least unknown. The variations between a "typical mine" with "average" values, to which the evaluations and analyses of the EIS are applied, and a real world mine are likely to be significant, yet the real world mine would be required to comply with the SPR.	As the commenter recognizes, the analysis utilizes typical mines and average values with a specific goal of understanding the overall impacts that the Alternatives would have on natural resources, and in order to be able to compare impacts across Alternatives and between Alternatives and No Action. The analysis recognizes that use of typical mines and average values for evaluation of impacts of the alternatives on water quality may be problematic when viewed from the perspective of an individual mine operator. The uncertainties raised by this issue are important and are recognized in the EIS in numerous places throughout the document. Appendix A to the RIA reviews cost effects of the various alternatives on small mines in particular.
OSM-2010-0021-0060	Ohio Department of Natural Resources	Studies used to evaluate the effects of coal mining on water quality (Table 4.2.1-6 on page 4-66) were the following: mountaintop mining/valley fills in five watersheds, the Upper Mud River in southwest West Virginia, the Pigeon Creek watershed in southern West Virginia, the Lower Cheat River basin in West Virginia, and 37 small West Virginia streams (impacts of mountaintop mining). These studies appear to be too narrowly focused for the basis of a major national rule revision. The DEIS, in its analyses, often uses a "typical mine" or "limited data." Such analyses, while informative, do not form a strong basis for formulating a rule that applies to all mines across the country.	OSMRE acknowledges that there is a heavy reliance on data describing the impacts of coal mining on natural resources from Appalachia, as this coal region has been the focus of more scientific interest. While these studies focus on Appalachia, OSMRE determined that development of a comprehensive, nationally applicable, stream protection rule would be the most appropriate and effective method of achieving the purposes and requirements of SMCRA, as well as meeting the goals set forth in the June 11, 2009, Memorandum of Understanding (MOU) among the U.S. Department of the Army, the U.S. Department of the Interior, and U.S. EPA implementing the interagency action plan on Appalachian surface coal mining. Streams are important

BENEFITS			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
			components of the hydrologic regime everywhere that streams are found, so there is no scientific reason to limit stream protection efforts to one region of the country.
OSM-2010-0021-0060	Ohio Department of Natural Resources	The extent of impacts used in the DEIS to compare alternatives is useful, but it is not clear that the precision necessary to make definitive conclusions is really attained. As an example, in the section dealing with "Stream Miles Downstream of Mine Sites Experiencing Water Quality Improvements" on pages 4-66 and 4-67, it is stated, " ... the analysis incorporates findings from the scientific literature to estimate how far downstream of a mine site negative effects of coal mining persist.. .. In general, these studies describe coal mining's effects on stream quality but do not specify the particular aspect of mine operations that generates the adverse effects. As such, the studies do not support an explicit analysis of the SPR elements' impact on downstream water quality .... While a review of the available literature identified many analyses of coal mining's impact on water quality, only one study identified the geographic extent of the adverse effects of mining on downstream water quality. Specifically, Petty et al. (201 0) estimates that the downstream effects of mining extend approximately 6.2 miles from the mine site .... Lacking site specific information on the extent of downstream water quality effects of mines, this analysis assumes, on average, that adverse effects of mining on water quality persist 6.2 miles downstream of mines for streams that cross the disturbed area of a mine site." Basing a national rule on a DEIS that relies on a value from one study for a number of calculations is not warranted.	Please refer to Master Response on Water Quality Benefits
OSM-2010-0021-0060	Ohio Department of Natural Resources	Much of the DEIS, in relation to hydrologic impacts, can be summarized by the narrative and tables on pages 4-70 to 4-83. Based on the information provided, benefits would appear to be limited. Focusing on the Appalachian Region, the Preferred Alternative (Alternative 8) in comparison to the No Action Alternative, would annuallya) Reduce stream miles filled by four (4),b) Restore one (1) ephemeral stream mile,c) Improve 174 stream miles downstream of mine sites, andd) Preserve one (1) stream mile downstream of mine sites.The DEIS states that "A reduction in	Chapter 2 of the EIS provides a discussion of the selection of Alternative 8 as the Proposed Action.

BENEFITS			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		production yields a mile of preserved downstream water quality annually." This is in the entire Appalachian region. The DEIS classifies these as "Major Beneficial" features of Alternative 8. (For the other six regions studied, the reduction in a) above would be zero (0), the restoration in b) would range from zero (0) to eleven (11), the improvement in c) would range from two (2) to fifty-one (51), and the preservation in d) would be zero (0).)The DEIS states on page 4-72, in relation to improvement in downstream miles, " ... the incremental downstream miles improved by the Action Alternatives represent a relatively small share of the overall water resources in affected regions. For instance, while several of the Alternatives could contribute to water quality improvements in roughly 174 stream miles in the Appalachian Basin, this can be compared to approximately 126,000 total stream miles in the region." In summation, the major rewrite and requirements of the proposed stream protection rule, in comparison to the projected Benefits, would appear to be extreme.	
OSM-2010-0021-0060	Ohio Department of Natural Resources	Chapter 4, Page 4-71, Stream Fills, 1st Paragraph "Interpretation of the incremental impacts of the rule and Alternatives on stream fill, miles of mined through streams, and downstream stream degradation, would benefit from contextual information that describes impacts on streams from coal mining under the No Action Alternative. For instance, estimates of the total number of stream miles that are mined through, filled and impaired annually by coal mining under current regulatory conditions would be helpful."The above statements are proof that the data needed to sufficiently evaluate stream impacts and data on mining operations operating under the current regulatory conditions were not used or available in the preparation of the DEIS, upon which the proposed SPR is based. In order to justify a full scale rewrite of coal mining regulations, actual background data and quantification of changes would be required.	As stated in the EIS following the quoted text, absent nationwide data regarding the historical effects of coal mining on streams filled, mined through, or degraded, the EIS describes a number of region- or site-specific studies that evaluate these types of coal mining impacts on streams. This information provides context for understanding the baseline levels of impacts to streams from coal mining. In addition, in response to public comment, the FEIS includes summaries of USACE permit data regarding permitted wetland and stream impacts from coal mining, as well as OSMRE data describing numbers of new mine permits and associated acreage of the new mine permits from 2005 and 2015.
NA	EPA	We recommend you consider including additional recent information from the scientific literature into the alternatives analysis, including stream restoration and impacts to streams and aquatic resources.	Additional references have been added to the analysis where possible, including USACE data on the location of permitted wetland and stream fills associated with mining permits
NA	EPA	There is scientific literature (especially in the Appalachian	OSMRE appreciates the recommendation by U.S.

BENEFITS			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		coal mining region) showing that restoration via a natural channel design (NCD) has not succeeded in meeting appropriate endpoints (e.g., attainment or maintenance of any existing, reasonably foreseeable, or designated use under section lOJ(a) or 303(c) of the Clean Water Act) of the affected stream segment following the completion of mining and reclamation. We recommend that the FEIS discuss the state of the current science of stream restoration and its limitations.	EPA. Information regarding adverse ecological impacts associated with natural channel design has been included in section 4.3.2.2 of the FEIS. Further, the reader is referred to the review of Bernhardt and Palmer (2011) for a detailed description regarding biological effects associated with natural channel design strategies.
NA	EPA	We recommend that the FEIS include a discussion on the use of appropriate ecological function indicators as restoration endpoints. It would be helpful for the FEIS to include a section that more thoroughly reviews the literature on restoration ecology to offer scientific commentary to help evaluate the likelihood of reaching the predicted outcomes of the alternatives.	Following publication of the proposed rule and DEIS OSMRE, US ACE and U.S. EPA have continued to work closely on the review of scientifically valid protocols that should be included as options for baseline stream assessment and monitoring. We have considered other protocols recommended by commenters as being scientifically defensible and already under implementation by states, territories, and tribes. We have added these as acceptable methods in the final rule. We have also identified and analyzed other captions that commenters suggested for assessing the baseline condition of and monitoring streams: the Rapid Bioassessment Protocol III (RBPIII), which is set out in the 1989 U.S. EPA Publication, "Rapid Bioassessment Protocols for Use in Streams and Rivers;" the Before-After-Control-Impact design (BACI); and hydrogeomorphic sampling protocols. We also considered using IBIs that were designed for perennial streams to assess the baseline condition of and monitor intermittent and ephemeral streams (as is occasionally done by Clean Water Act authorities). More detail on the pros and cons of each method can be found in the preamble to the final rule at Section IV. N. *The Rule Should Not Require the Use of Multimetric Bioassessment Protocols to Establish Baseline Ecological Stream Function and Stream Restoration Criteria.* Ultimately, as provided in the final rule at sections 780.19(c)(6)(vii) and 784.19(c)(6)(vii), we determined that the best technology currently

BENEFITS			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
			available for baseline assessment and monitoring purposes for perennial streams is the use of IBIs or other equally scientifically defensible stream assessment protocols developed and applied by states, territories, and tribes. We also determined that it is not currently appropriate to use protocols developed for perennial streams to assess the baseline condition of and to monitor intermittent streams. Some states and regions have developed indices of biotic integrity or bioassessment protocols for intermittent streams. In those instances, final sections 780.28(g)(3)(iii) and 780.19(c)(6)(vii) and their counterparts in sections 784.28 and 784.19 require use of those protocols to assess the baseline condition of and to monitor intermittent streams. Where scientifically defensible protocols do not yet exist in a state we are requiring baseline assessment and monitoring of these streams using a description of the water quality, water quantity, stream channel configuration, a quantitative assessment of the streamside vegetation, and an initial cataloging of the stream biota. For further detail, please see our discussions of sections 780.19, 780.27, 780.28, 816.56, and 816.57 in the preamble to the final rule. Additional studies discussing the current state of restoration science have been incorporated in section x of the EIS. As discussed in the preamble to the final rule, OSMRE recognizes that stream restoration and creation is an emerging area of scientific study and that in some cases the reconstruction of functional stream channels on mined land can be difficult. However, OSMRE did not expect restoration activities to return precisely the ecological function that was there before mining. Based upon scientific studies and our experience, we conclude it will not be impossible to comply with the ecological restoration requirements of

BENEFITS			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
			this rule. This is, in part, because we have changed the final rule (Preferred Alternative) with respect to how to demonstrate the restoration of ecological function. We also note, however, that one of the purposes of SMCRA is to ensure that "surface mining operations are not conducted where reclamation as required th[e] Act is not feasible" and that the Act therefore requires a permit applicant to demonstrate that "reclamation as required [by SMCRA] and the State or Federal program can be accomplished under the reclamation plan contained in the permit application[.]" If reclamation of a stream cannot be accomplished, then the permit applicant will need to adjust its mining or reclamation plan to ensure the reclamation standards can be met before the regulatory authority can approved its permit.
NA	EPA	In Chapter 3, baseline summaries of streams within each of the coal resource regions are limited to intermittent and perennial streams only. Chapter 4's analysis of the effects of alternatives on surface waters is not broken out by the different stream types. In the absence of such information, it is difficult to evaluate the relative effects of one alternative versus another in protecting all stream types.	The table (3.5-1) was limited to only intermittent and perennial streams because the hydrography dataset for ephemeral streams is known to be incomplete. This has been clarified in the table footnotes. The analysis presented in Chapter 4 of the FEIS has been revised to specify impacts to intermittent and perennial streams as distinct from ephemeral streams
NA	EPA	Page 4-55, Table 4.2. 1-1 and 4-57: With regard to baseline monitoring, while it may be valid to compare relative merits of the alternatives on baseline water quality across mine regions, the alternatives should also be evaluated on the magnitude of impact relative to baseline water quality within a region or permit area. Baseline water quality may already be impacted and near an ecological threshold where even minor additional degradation could lead to disproportionate biological effects.	OSMRE agrees with this comment that the extent to which the water quality improvements generated by the alternatives reduces ecological injury depends on the baseline water quality at a site, and that baseline water quality at a site varies not only across regions but within regions. As data are not available on specific locations of future mines that will be subject to the requirements of the rule, the baseline water quality at future mine sites is uncertain. As a result, the EIS quantifies the linear extent of stream over which water quality would be improved by the alternatives (based on regional averages for the numbers of streams

BENEFITS			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
			crossing mine sites) and describes qualitatively that the magnitude and implications of the water quality improvement are site-specific.
NA	EPA	Page 4-67, paragraph I: As noted in the DEIS, use of results from a single study to estimate downstream effects of mining (6.2 miles) [Petty et al. 2010] adds significant uncertainty to regional estimates because of differences in mining types/ intensity, composition, precipitation, topography, etc. The level of uncertainty involved undermines the model results on lengths of downstream impacts across regions.	Please refer to Master Response on Water Quality Benefits.
NA	EPA	Page 4-70, bullet 2: The scientific literature highlights the challenges of stream restoration. Specifically, restored ephemeral channels have shown to have impaired ecosystem functions, as later noted on 4-93 and 4-94 (Fritz et al. 2010). There is also little evidence that restoring stream habitat and geomorphology would similarly restore water quality.	The EIS does not explicitly state that restoration of ephemeral streams will fully restore ecosystem function and water quality. Section 4.2.1 includes estimates of the length of ephemeral streams that will be restored under the Alternatives that would not have been restored under the No Action Alternative. This metric, while imperfect, provides information about the scale of stream improvements that are expected to occur.
NA	EPA	Page 4-1 34, paragraph 4: Provide more information to demonstrate that complete restoration of hydro logic form and ecological function can be accomplished for headwater steams.	As discussed in the preamble to the final rule, OSMRE recognizes that stream restoration and creation is an emerging area of scientific study and that in some cases the reconstruction of functional stream channels on mined land can be difficult. However, OSMRE did not expect restoration activities to return completely or precisely the ecological function that was there before mining. Based upon scientific studies and our experience, we conclude it will be possible to comply with the ecological restoration requirements of this rule. This is, in part, because we have changed the final rule (Preferred Alternative) with respect to how to demonstrate the restoration of ecological function. We also note, however, that one of the purposes of SMCRA is to ensure that "surface mining operations are not conducted where reclamation as required the th[e] Act is not feasible" and that the Act therefore requires a permit applicant to demonstrate that

BENEFITS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
			"reclamation as required [by SMCRA] and the State or Federal program can be accomplished under the reclamation plan contained in the permit application[.]" If reclamation of a stream cannot be accomplished, then the permit applicant will need to adjust its mining or reclamation plan to ensure the reclamation standards can be met before the regulatory authority can approved its permit.
OSM-2010-0021-0696	Murray Energy Corporation	Restoration endpoints should not be based strictly on pre-mining conditions and should consider site-specific factors potentially inhibiting stream recovery. Appropriate upstream conditions must also be taken into consideration to the extent restoration requirements in the final rule require establishing pre-mining conditions. This would account for non-mining factors in the watershed and variability over time. Determination of pre-mining conditions and subsequent reclamation goals should not only consider conditions on the mine site but also include upstream control sites that are not mining-impacted	Site specific factors that would potentially inhibit recovery are considered. Adequate baseline characterization, as required under the rule, will allow identification of these situations. Section 780.28(e)(3)(iii) requires that, when mining through a degraded stream, the mining "[w]ill not further degrade the form, hydrological function, biological condition, or ecological function of the existing stream segment." Final paragraph (c)(2)(vi) of 780.28 allows an exemption to the requirement to restore premining drainage pattern and stream-channel configurations if the regulatory authority finds that a different pattern or configuration is necessary or appropriate to replace a stream that was channelized or otherwise severely altered with a more natural and ecologically sound drainage pattern or stream-channel configuration.
OSM-2010-0021-0696	Murray Energy Corporation	Furthermore, in setting reclamation goals, regulatory agencies should not use aquatic life designated use attainment standards as the endpoint for reclamation success. In establishing designated use attainment conditions, states utilize ecoregion "reference sites" based on sites essentially free from anthropogenic input. These ecoregion reference sites will not reflect site-specific pre-mining or post-mining conditions and likely will not be located in the same watershed as (much less immediately upstream of) a reclaimed stream reach. Thus, the use of ecoregion reference sites in determining reclamation recovery is inappropriate for the reasons presented above.	No changes were necessary within the EIS in response to this comment. These comments and other similar considerations are discussed in detail in the preamble to the final rule. Please see Section IV.N. N. *The Rule Should Not Require the Use of Multimetric Bioassessment Protocols to Establish Baseline Ecological Stream Function and Stream Restoration Criteria.*
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.5.3.1 and Table 3.5-8, p. 154 "A review of USGS water use data for the years 1985 to 2000	The Water Usage section in Chapter 3.5.3.1 has been updated to include USGS data through

BENEFITS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		indicates that the total share of the population supplied by a public water supplier is increasing while the proportion of the population that is self-supplied is decreasing (Table 3.5-8) (USGS, 2013a)." Based upon this data, the overall susceptibility of localized populations to be affected by groundwater impacts related to mining may be decreasing. OSMRE should validate this conclusion by collecting more recent groundwater data (i.e. 2001 through 2016). If true, potential groundwater impacts to the wells from individual suppliers are indeed decreasing.	2010, as opposed to 2000, to appropriately characterize domestic water supply
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.8.2.1, p. 3-244 Several studies highlight alternatives and improvements to the USDA-USFS Ecoregion Classification scheme that was developed in the 1990s (see, e.g., Sleeter et al., 2013, Omernik and Griffith, 2014). OSMRE should examine more closely how different approaches—many of which involve support from federal resource agencies—provide more accurate information on ecoregions in US coal mining areas. In the context of modern mining practices and federal regulation, land classification approaches that predict land-use change and the associated economic values of different types of changes (including restoration) and that are spatially detailed enough to be ecologically meaningful and based on sound science (see, e.g., Lewis et al., 2012) are needed to improve the DEIS and Proposed Rule	Section 3.8.2.1 of the DEIS provides a general description of the ecological character of each coal region using the USDA-USFS Ecoregion Classification Scheme as a guide. Modifying the Ecoregion Classification scheme as recommended by the commenter would not impact the analysis. OMSRE reviewed Lewis et al., 2012, which parameterized an econometric model of land-use change to project future land use to the year 2051 at a fine spatial scale across the conterminous United States under several alternative land-use policy scenarios. Their results generally showed that alternative land use policy scenarios had little effect on future trends relative to business-as-usual. While interesting, the Lewis model was not easily available for our analysis. A note has been added to Chapter 3 that models of this type are being developed.
OSM-2010-0021-0696	Murray Energy Corporation	Federally Protected and Regulated SpeciesSection 3.8.2.2, p. 3-246OSMRE's analysis regarding which threatened and endangered species may be affected by mining operations should be included in the DEIS to afford independent verification of OSMRE's findings. The absence of this information undermines OSMRE claims that the DEIS represents a clear and transparent analysis.	The level of detail in the DEIS was sufficient but has been updated. The DEIS analyzed regional distributions of critical habitat, as well as the distribution of forest cover. Additional detail on species and habitats by region are contained within the Biological Assessment and Biological Opinion for the Stream Protection Rule.
OSM-2010-0021-0696	Murray Energy Corporation	It is unclear whether the DEIS refers to all listed species in all of the coal region's states, or just listed species within the coal mining areas, which would be smaller in number...Additionally, it is unclear how recent these data are. The DEIS should delete discussions of species	The species discussed were determined in coordination with the U.S. Fish and Wildlife Service on area affected by the proposed rule. Appendix F of the FEIS lists the final species list used in the ESA Section 7(a) consultation for the

BENEFITS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		throughout the southeast if not relevant to species in the coal region, itself. An impacts analysis should be limited to listed species that occur in the coal region that may actually be impacted by coal mining activities, so an additional step in this section should be to identify listed species in the coal region that may be impacted by mining activities.	SPR. The final Biological Assessment and Biological Opinion will be available on the OSMRE website.
OSM-2010-0021-0696	Murray Energy Corporation	Evaluation of Section 3.11.1 also indicates that the question of whether coal mining detracts from (or in some cases may actually contribute to) the aesthetic quality of a region varies widely from region to region, particularly with respect to the potentially divergent viewpoints of nonresidents and residents. Stakeholders will not necessarily view the aesthetic qualities of an area in the same way, and the visual impacts of mining will not necessarily be uniformly negative. The BLM visual resources management (VRM) system is briefly described and may represent a process by which the aesthetic values of manmade resources could potentially be assessed. However, no broadly applicable mechanism is suggested in this document by which the relative importance of manmade features (which may include active or historical coal mines) to the overall visual aesthetic quality of a region or location can be balanced with an assessment of natural features, while giving due consideration to the potentially sharply contrasting aesthetic values of residents and visitors.... Many of those wildlife areas were mined pre-SMCRA without federal regulations and yet are now considered pristine wildlife refuge The DEIS mentions these sites but does not give them any weight in the analysis. They constitute the major wildlife refuge areas in the Illinois Basin and thousands of visitors visit them for visual resource reasons. Enhanced reclamation ensures better long-term recreation opportunities. Riparian zones, erosion control, and better vegetation already in place under the current SMCRA and CWA rules result in in an environmental lift that outweigh any temporal effects by any reasonable measure.	Providing a broadly applicable mechanism to assess the value of manmade resources versus naturally occurring resources is outside of the scope of this effort. However, OSMRE has qualitatively evaluated the potential beneficial effects the alternatives would have on water quality, forest resources, and biological resources from proposed AOC and reforestation requirements. Better water quality and landscapes that are more representative of natural conditions for the site are environmentally preferable and improved aesthetics are assumed to also result. We do not disagree that the mentioned areas provide a valuable and aesthetically pleasing resource.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.0.3.9, p. 4-12 The "Moderate Beneficial" impacts anticipated in Appalachia and the Colorado Plateau under most of the alternatives are not defined, but certainly, many recreational activities in	The commenter is assuming that more stringent proposed revegetation requirements will negatively affect recreational activities, due to increased requirements related to approval of

BENEFITS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		which people who live in these areas actually participate are dependent upon the post-mining land use of mining operations (golf, hunting on land that can be traversed, elk viewing, school athletics out of flood zones, etc.).	post-mining land use. However, the proposed revegetation requirements would re-establish native vegetation, which supports local species for recreational viewing and hunting and more natural conditions for activities such as hiking, and wildlife viewing. OSMRE acknowledges that there would be an adverse impact to recreational hunting, any short-term effect to hunting would be minimal relative to the long-term benefits to many are recreational activities that are dependent on land use changes post-mining but expects that the Proposed Action would net the predicted benefits described in the FEIS.
OSM-2010-0021-0696	Murray Energy Corporation	Recreation Section 4.0.3.9, pp. 4-13 to 4-19, Table 4.0-2 through Table 4.0-8 It is not clear how OSMRE determined the impact for surface mining versus underground mining, or if OSMRE prepared the tables for surface mining and simply assumed underground mining to be the same. The two should be separated, as there should and will be differences in impact between surface and underground mining. Surface mining has an immediate and direct effect on surface topography and native soils, visual resources, recreational opportunities, and biological resources. Underground mining, on the other hand, has limited visual impact and does not require relocation of native soils or vegetation.	Underground mining and surface mining are analyzed separately in the EIS with regard to changes in coal production under the SPR relative to the No Action Alternative and with regard to costs and benefits to natural resources that may accrue. These collective impacts are then used to as the basis for determinations about overall impacts to the resource categories in the tables cited by the commenter. The commenter is correct in that surface mining has an immediate and direct effect on a variety of resources. In addition to associated surface facilities, underground mining can also impact surface topography through subsidence, which can have an immediate impact on visual resources and surface topography.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.1.1, p. 4-51, first paragraph Surface mining permits issued between October 2001 and June 2005 affected approximately 535 miles of streams… The majority of these "stream" miles are dry, ephemeral ditches or swales.	The comment provided no data to support the assertion that the majority of these impacts were within conveyances that did not qualify as streams, therefore no change was warranted to the EIS text. Additionally, the Corps of Engineers data provided for later years in the FEIS indicates that impacts to streams continue to occur.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.1.1, p. 4-51, third paragraph "An unintended consequence of the storage function provided by sediment ponds is that the impoundment of the waters affects the timing and volume of water received	Thank you for the comment. OSMRE acknowledges that there are legitimate reasons for constructing impoundments; the benefits mentioned in the comment are among the

BENEFITS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		downstream from the pond; peaks and lows in the hydrograph are smoothed out due to the impoundment and controlled release of the water." This is only one possible consequence of delayed release of flows and is generally less applicable to ephemeral streams than to larger perennial streams. Delayed discharge of peak flow can also contribute to less erosion and channel instability by reducing peak flow energies. This statement fails to recognize there can be Benefits to the impoundments, such as reduced sediment loads, increased infiltration, and increased base flows, especially in semiarid or arid environments.	reasons that these structures are used. However, these structures also have negative consequences such as resuspension and mobilization of sediments and associated contaminants during heavy precipitation and overflow events. No change is required in the FEIS text.
OSM-2010-0021-0696	Murray Energy Corporation	This section describes the scientific research referenced and the procedures used by OSMRE in calculating stream impacts/Benefits using the model mines on a per ton basis and then extrapolating the results across the coal-producing regions based on total tons produced in the region. Page 4-66 includes a qualifying statement that a majority of the water quality research has been performed in the Appalachian Basin, and that the studies do not support an "explicit analysis" of the Proposed SPR's impact on downstream water quality. The section cites one particular study perform by Petty, et.al, on the Lower Cheat River in West Virginia, where it was theorized that the downstream effects from mining extend approximately 6.2 miles from the mine site. This 6.2 value is then used to calculate downstream effects for all coal regions across the U.S. apparently without any modifications to adjust for differences in topography, geology, or hydrology between the regions.	Please refer to Master Responses on Water Quality Benefits and Model Mines Analysis.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.1.3, p. 4-66, first paragraph "The analysis uses the following method to estimate the number of improved stream miles downstream of mine sites. First, the analysis incorporates findings from the scientific literature to estimate how far downstream of a mine site negative effects of coal mining persist...." Except for references to non-peer reviewed literature, OSMRE relies on one published technical study predicting water quality impacts downstream of a mine in the Appalachian Basin to draw conclusions about downstream impacts associated with mining throughout the U.S. OSMRE fails to acknowledge that the environmental conditions in the Appalachian Basin are	Please refer to Master Response on Water Quality Benefits

BENEFITS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		entirely different from conditions in other mining regions such as in Wyoming and Montana, which have a much greater buffering capacity. OSMRE's approach is grossly simplistic and inappropriately generalizes an important benefit/cost consideration with respect to implementation of the Proposed Rule.	
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.1.3, p. 4-66, Table 4.2.1-6, "Petty et al., 2010" Petty et al. used extensive statistical analyses to establish an index of mining intensity, and found a negative correlation between mining and benthic invertebrates. Petty et al. only identified benthos to the familial level, and based all of their results on this high-level identification. It would be very difficult to associate every taxon in a family with a particular perturbation. For example, the family Chironomidae (Order Diptera) contains genera that are highly intolerant, as well as highly tolerant to pollution (and often specific types of pollution). This is true with many families of benthos, including mayflies, stoneflies, caddisflies (the EPT taxa index used). Tolerance values are often misleading when assigned to genera (cf. species), so decisions based on family-level identifications are questionable.	The use of family level indicators is common in biological assessments. However, the study of Petty et al., 2010, did not only consider family abundance, but also calculated a biological response for species richness within the families selected as indicators. Therefore, consideration was give not only to numbers of individuals, but also to the diversity of the biological community.
OSM-2010-0021-0696	Murray Energy Corporation	Analytic Methods for Surface Water Resources Section 4.2.1.3, p. 4-67 Lacking site specific information on the extent of downstream water quality effects of mines, this analysis assumes, on average, that adverse effects of mining on water quality persist 6.2 miles downstream of mines for streams that cross the disturbed area of a mine site. If the model mine analysis can only be based on hypothetical assumptions and cannot be calibrated to or validated by actual mine operations, it certainly cannot be considered to be the best available science, particularly because hundreds of actual mines with actual data have been presented to OSMRE over the years. Using hypothetical information when actual data is available is not best available science or the "hard look" demanded by NEPA.	Please refer to Master Response on Model Mines Analysis.
OSM-2010-0021-0696	Murray Energy Corporation	Analytic Methods for Surface Water Resources Section 4.2.1.3, p. 4-67, second and third paragraphs and footnote 17 OSMRE's stream crossing analysis was completed by mapping sources, predominately based on USGS high resolution National Hydrography Dataset, to estimate the	Section 4.2.13 has been revised to be more clear about the methodology used to quantify potential impacts of the Alternatives on streams. The commenter is correct that the calculations of downstream miles of stream

BENEFITS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		number of streams flowing in surface and underground mine permit areas in each mining region. Then, OSMRE counted the number of times that perennial and intermittent streams intersected the mine permit area and divided the result by two. Ephemeral streams were not included in the work. OSMRE did not verify this approach by comparison to representative mining areas in different states; thus, the approach is highly uncertain with respect to actual environmental conditions. Preliminary comparisons indicate that OSMRE has grossly over-estimated the number of stream crossings on mine permit lands.	likely to benefit from the Alternatives include quantified river miles only for intermittent and perennial streams. As such, to the extent that downstream ephemeral streams would benefit from reduced impairments to water quality, these benefits may be understated. This point has been clarified in the FEIS.
OSM-2010-0021-0696	Murray Energy Corporation	Analytic Methods for Surface Water Resources Section 4.2.1.3, p. 4-68, Table 4.2.1-7 The 7.2 streams intercepted by the model Northern Rocky Mountains mine is not representative of mines in Montana, North Dakota, or Wyoming. It is rare for mines in this area to mine through intermittent or perennial streams, which would generally require analysis under the alluvial valley floor rules	OSMRE agrees that mining under or through intermittent or perennial streams in western mines is not as common as it is in other regions of the country. Indeed, those characteristics are exhibited in our western model mines. We conducted an analysis that intersected 17 current and historic mine locations in Wyoming and Montana with USGS intermittent and perennial stream locations. Using assumptions about the disturbed area for mines in this region from the model mines analysis, we found that an average of 7.2 streams intercept Western mine sites. However, we note that the size of the surface mine in the Northern Rocky Mountains and Great Plains Region is larger than all other regions, both in terms of disturbed acreage as well as annual coal production. When these factors are considered, we find that coal mining in the Northern Rocky and Great Plains Region affects much less stream miles for each ton of coal produced than in Appalachia (0.04 streams affected per ton of coal mined in the Northern Rocky and Great Plains Region versus 0.5 to 4.8 streams affected per ton in Appalachia) Additional information has been added to section 4.2.1 of the EIS to clarify this methodology.
OSM-2010-0021-0696	Murray Energy Corporation	Analytic Methods for Surface Water Resources Section 4.2.1.3, p. 4-68, second paragraph "[T]he estimate of total downstream miles affected at a	This assumption is appropriate and provides for greater comparison across all regions by standardizing the assessment metric. Section 4.2.1.3 of the FEIS acknowledges that the total

BENEFITS			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		given mine implicitly assumes no downstream convergence. This assumption allows for comparison across regions that reflects the stream density of different regions. However, it is likely that for some mines, streams crossing the mine ultimately converge. In such cases, the total number of stream miles experiencing improved water quality may be overestimated." OSMRE's assumption of no downstream convergence grossly overestimates the number of stream miles affected, especially for regions where high-density streams are present. Despite acknowledging this limitation, OSMRE inexplicably relies upon the results to draw conclusions about downstream surface water impacts.	number of stream miles experiencing improved water quality may be overestimated by assuming no downstream convergence. However, it is also possible that the level of the water quality improvement may also be greater downstream of the convergence of two improved streams.
OSM-2010-0021-0696	Murray Energy Corporation	Results of Quantitative Analysis of Surface Water Impacts Section 4.2.1.4, p. 4-70, first bullet. Any Benefits of stream filling reduction will be limited to the Appalachian region. This section omits the fact that the drastic number of reduced "stream (primarily ephemeral)" filling will make most of Appalachia unmineable as a result of this rule. However, the fourth bullet point does directly acknowledge this when it says, " . . . Appalachia, the region anticipated to experience the greatest reduction in surface coal mining activity...."	The anticipated reduction in future coal production is related to total current production. Therefore, coal mining regions currently demonstrating higher levels of coal extraction, such as Appalachia, will experience the greater absolute reduction in coal production under the SPR.
OSM-2010-0021-0696	Murray Energy Corporation	OSMRE fails to explain how the two tables differentiate between surface and underground mining. Table 4.2.1-9 summarizes annual stream miles not filled, but does not specify if the data include ephemeral, intermittent, and/or perennial streams. Table 4.2.1-9 shows that only four stream miles will not be filled annually compared to the current rule; the improvement relative to current regulations is unremarkable. Similarly, Table 4.2.1-10 shows a marginal improvement of 29 miles of restored ephemeral streams (under Alternative 8).	Table 4.2.1-9 presents the total number of perennial and intermittent streams that would not be filled relative to the No Action Alternative. The title of Table 4.2.1-9 has been updated to clearly define that the values listed represent perennial and intermittent stream miles not filled.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.1.4, p. 4-73, Table 4.2.1-10 The conclusions presented here on miles of stream restored compared to the No Action Alternative are based on the faulty assumption that current reclamation does not restore ephemeral streams. This is not correct, at least for western arid/semiarid mine sites.	It is true that our analysis of the impacts of the rule on ephemeral stream restoration requirements may underestimate the level of ephemeral stream restoration that may be occurring in Western mines under the No Action Alternative. We reviewed permits in the Western region as part of the RIA/EIS analysis, and found that found that the actual number of

BENEFITS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
			ephemeral streams that were restored was small (approximately 10 to 20 percent). Therefore, the analysis makes the conservative assumption (more likely to overstate impacts than understate them) that no efforts to restore ephemeral streams would occur in the Western region under Alternative 1 (No Action).
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.1.5, p. 4-82 The benefit results summarized for Alternative 8 are few in the Colorado Plateau, Gulf Coast, and Northern Rocky Mountains/Great Plains regions. Because the benefits would be minor, the purpose and need, as defined under NEPA, does not seem to support a Proposed Rule in those regions.	The benefits for Alternative 8 are actually moderate in the Colorado Plateau, Gulf Coast, and Northern Rocky Mountains/Great Plains regions. OSMRE determined that development of a comprehensive, nationally applicable, stream protection rule would be the most appropriate and effective method of achieving the purposes and requirements of SMCRA, as well as meeting the goals set forth in the June 11, 2009, Memorandum of Understanding (MOU) among the U.S. Department of the Army, the U.S. Department of the Interior, and U.S. EPA implementing the interagency action plan on Appalachian surface coal mining.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.1.5, p. 4-82 Four fewer stream miles are filled annually... Improved mining practices lead to improved groundwater and stream quality in 174 stream miles annually... OSMRE fails to explain the cost associated with achieving four fewer miles of filled streams and provide a sufficiently robust analysis of the costs and Benefits likely realized under current regulations and adoption of the Proposed Rule.	Please see Industry Compliance Cost analysis in Chapter 8 of the RIA.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.1.6, p. 4-83The effects of Action Alternatives on water resources are beneficial, themselves comprising minimization and mitigation measures in many cases. Thus, potential minimization and mitigation measures are not relevant to this evaluation. OSMRE fails to provide the technical foundation for its conclusion. OSMRE states that the groundwater "issue" is described in Section 4.2.1.1. However, Section 4.2.1.1 did not present any definitive information with regard to various studies linking groundwater contamination to coal mines, or differentiating between effects of groundwater by coal mining versus other extractive industries or sources. It appears that the weight of the benefit/improvement is summarily based upon the	OSMRE conducted qualitative groundwater assessment of SPR impacts. A primary metric used in these assessments is groundwater utilization in specific mining regions. As the SPR is not expected to negatively impact groundwater, OSMRE determined beneficial impacts based on regional dependence on groundwater. It is unclear why the commenter states that monitoring and tighter restrictions would not be necessary even if groundwater use is decreasing.

BENEFITS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		percent of residential (potable) groundwater usage and not improvements to groundwater overall. If solely based on residential groundwater use, one could argue that across most regions, the overall number and percentage of people utilizing well water for a primary drinking water source is decreasing, thereby one could make the argument that tighter restrictions and monitoring is not necessary.	
OSM-2010-0021-0696	Murray Energy Corporation	Effects of the Current Regulatory Environment (the No Action Alternative) Section 4.2.2.1, p. 4-89 "The abundance and diversity of macroinvertebrate species is, therefore, indicative of the relative health of a stream. For example, a stream that contains robust populations of pollution-sensitive macroinvertebrate species can be seen as healthier (i.e., less impacted by mining) than a stream dominated by pollution-tolerant species." This discussion offers unsupported generalizations -e.g., "healthier (i.e., less impacted by mining)" - and sweeping opinions that no adverse impacts in or near streams can be tolerated. OSMRE instead must recognize that the Benefits of coal production may outweigh the costs of environmental effects in certain circumstances.	The text is merely explaining that the reduced presence or absence of pollution-sensitive macroinvertebrate species indicates that a stream has been impacted, and in the context of an analysis of mining impacts that a stream with more pollution sensitive species would indicate that the stream had received fewer impacts. No change is necessary.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.2.2, p. 4-96, first paragraph"In summary, existing regulations under the No Action Alternative contain many mechanisms for ensuring protection of fish, wildlife, and related environmental resources but coal mining practices occurring under these regulations continues to have adverse effects on aspects of the biological, chemical, and physical environment. These adverse impacts include: fragmentation of habitats; degradation of habitat quality; exposure of biota to changed chemical conditions in aquatic environments; and permanent loss of terrestrial and aquatic habitat. Adverse impacts would continue to occur, as described above, with all mining methods and in all coal regions under the No Action Alternative."Using OSMRE's own analysis (though fraught with errors and uncertainties) the enforcement of current mining regulations would achieve a comparable level of environmental protection as the Proposed Rule.	Several aspects of the SPR will directly address the concerns expressed in the comment. Specifically, the revegetation requirements would reduce habitat fragmentation by promoting contiguous native habitat, which important for wildlife. Further, the increased monitoring will help identify contamination issues in downstream waterways. Early identification and rectification of stream contamination would prevent additional loss of downstream habitat or biota.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.2.2, p. 4-98 Throughout this section, OSMRE advances the concept that reforestation is a better goal than cropland or pasture for	Please refer to Master Response on Reforestation.

BENEFITS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		post-mining land-use in reclamation: "The Forestry Reclamation Approach." OSMRE does not provide a sufficiently detailed discussion of how near-term revegetation for erosion control can be succeeded by a native and diverse forest cover. Potential exceedances in total suspended solids (TSS) are a cause for caution in the approach to replanting trees. OSMRE should discuss this issue more fully along with cost projections for such measures.	
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.2.2, p. 4-98 "Impaired habitat conditions adversely affect the ability of a coal mining region to support particular species and may in turn negatively affect wildlife-related recreational activities, including hunting and wildlife viewing (as described in Section 4.3.3)." This section does not consider "edge effect" Benefits and does not take into account the fact that elk, wild turkeys, coyotes, etc. have all been successfully reintroduced to Appalachia on reclaimed mine sites. Wildlife viewing is actually a developing industry on reclaimed surface mine sites in Appalachia.	The commenter is assuming that more stringent proposed revegetation and reforestation requirements will negatively affect recreational activities, particularly hunting. This statement suggested that disturbing and replacing habitat is better than not having disturbed the habitat at all. The proposed revegetation requirements would re-establish native vegetation, which supports local species targeted for hunting. Reforestation can take a decade or more to occur, but mountain forest landscapes are highly preferred for many recreational activities including hiking, hunting, wildlife viewing, and others. While it is uncertain that there would be an adverse impact to recreational hunting, any short-term effect to hunting would be minimal relative to the long-term Benefits to many recreational activities, including hunting, that could occur by returning the landscape to its natural state with respect to vegetation. While the edge effect is a documented feature that has been shown to enhance biodiversity, the wildlife Benefits of contiguous native habitat cannot be understated.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.2.2, p. 4-99, second bullet" Alternatives 2, 3, 4, 5, 7, and 8 additionally specify that the revegetation be completed using only native species unless the postmining land use is actually implemented before the end of the revegetation responsibility period." OSMRE fails to define the revegetation responsibility period.	The responsibility period corresponds to the period prior to the final bond release. Please see Chapter 2 of the EIS for additional information.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.2.2, p. 4-101, first three bullets The "benefit" attributed to the required riparian zone is not	OSMRE acknowledges that the there are similarities between the No Action Alternative and the Action Alternatives, including the

BENEFITS			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		truly a benefit of the alternatives because revegetation already occurs under existing regulations. In addition, the 100- and 300-ft riparian zones cannot be realized for most ephemeral streams in the arid/semiarid West.	Preferred Alternative. The Preferred Alternative adds increased protection and restoration to perennial, intermittent, and ephemeral streams. The Preferred Alternative would require the establishment of a 100 foot or wider riparian corridor around all streams following the completion of mining. The revegetation requirements are described in detail in Chapter 2. Briefly: "The corridor must be comprised of native species, including species with riparian characteristics. The permittee must plant native trees and shrubs in areas that are forested at the time of permit application or that would revert to forest under conditions of natural succession." The ultimate goal of the SPR is to return native vegetation to mining impacted areas.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.2.3, p. 4-102, second paragraph "To estimate this acreage, the analysis uses available historical land cover data (the oldest comprehensive dataset was 1992) at sites that have since been mined. As such, Table 4.2.2-2 summarizes the land cover in 1992 that was present at mine sites that were developed after 1992 in each of the coal regions in order to understand premining land cover conditions in each region." OSMRE should explain why it uses outdated data sets, rather than more recent data, to determine the difference between baseline conditions and mine land forest conditions. As a general rule, land cover that is forested in many parts of the U.S. is decreasing, not increasing. At a minimum, the analysis should include a trend analysis addressing forestation and deforestation in mining regions. National land cover datasets are also available from 2006 and 2011.	The purpose of the analysis referenced in this comment is to determine the extent to which historic mine sites have required cutting forest, and ultimately reforested as part of reclamation. In order to reflect pre-mining conditions, OSMRE referenced an older version of the National Land Cover Dataset (NLCD), specifically from 1992, along with data on location of mines developed since 1992. This analysis informed an estimate of the average acreage of forest cut per ton of coal produced in each region. OSMRE agrees that coal mining is not the only source of deforestation in coal regions and therefore did not estimate impacts based on trends in forest land cover using the NLCD data over time. OSMRE assumes, however, that forests that are cut for other purposes (e.g., residential, recreational, or industrial development) are not the same sites likely to support coal mining activity in the future. Thus, OSMRE assumes that the rate at which forest was cut at mine sites in the recent past is reflective of the rate at which future mine sites will require cutting, and ultimately replanting, forest.

OSM-2010-0021-0696	Murray Energy Corporation	Analytic Methods for Assessing Forest Land Cover Section 4.2.2.3, p. 4-107, Table 4.2.2-3 OSMRE observes that 70% of post-mine land in the Appalachian Basin is reforested (No Action Alternative). If this is the case, OSMRE should clarify how reforestation using improved methods could be 37% for the No Action Alternative for the Appalachian Basin. There appear to be errors in OSMRE's assumptions and calculations.	To clarify, the EIS text describes that 70% of post-mine land in the Appalachian Basin is generally reforested (under the baseline No Action Alternative). However, only a fraction of the reforested area applies improved reforestation methods. The 70% and 37% estimates both represent a fraction of the total disturbed area at the mine site and are therefore not additive.
OSM-2010-0021-0696	Murray Energy Corporation	Analytic Methods for Assessing Forest Land Cover - Methods for Assessing Preserved Forest Acres Section 4.2.2.3, p. 4-108 There are too many variables in current mining practices across the different mining regions to base analyses on "Model Mine" or "typical" scenarios.	The model mines were tailored to each region. Please see Master Response on Model Mines Analysis.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.2.7, p. 4-114, first bullet"Preserved and improved forests result in increased carbon storage potential, improved habitat quality, and improved conditions for recreational and aesthetic Benefits (Stephenson et. al., 2014)"The paper by Stephenson et al., was specifically about carbon storage, and data were presented in that paper to support the concept. Habitat quality and recreational opportunities were mentioned as possible side effects with no data presented in support. Forests support certain wildlife more than others. For most species of recreational interest in the eastern U.S., a habitat matrix consisting of a diversity of habitat types offers the most hunting and wildlife viewing opportunities. A mix of forests, grasslands, and shrub/scrub habitats at varying stages of succession will support the greatest number of species.	OSMRE appreciates the verification of the statement in the text. It is reasonable to assert that improved forest habitat will benefit aesthetics and recreational viewing relative to degraded or improperly restored habitat. OSMRE also acknowledges the importance that habitat diversity has on wildlife and associated recreational activities. To that end, a primary component of the SPR is the re-establishment of native habitat, such that it mimics natural plant assemblages, which undoubtedly is comprised of the habitat diversity as cited by the commenter.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.2.7, pp. 4-114 to 4-115 OSMRE's entire discussion of impacts to biological resources is unclear. OSMRE fails to define adequately the terms "impacts," "Benefits," and "negative effects" and often uses the terms interchangeably. The entire section should be revised to state explicitly what is meant by "beneficial" and "negative" impacts, and then those terms should be used only where applicable.	OSMRE appreciates the commenters concern regarding the definitions of the impact characterization categories. We have more clearly defined the geographic scope and duration of the impact for each resource in section 4.0.3 and in resource-specific sections of chapter 4. The expanded definitions better articulate how impacts were determined for each resource in the FEIS. Under NEPA, “impacts” and “effects” are synonymous.
OSM-2010-0021-0696	Murray Energy Corporation	442. Assessment of Quantified Impacts to Topography, Geology, and Soils Section 4.2.3.3, p. 4-141, footnote 32	Section 4.2.3.3 recognizes that the slope analysis is simplified. An analysis of the

BENEFITS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		"This is an oversimplification because topography represents the three-dimensional arrangement of physical attributes (shape, elevation, and volume), and typically includes an analysis of aspect (direction of slope) of a land's surface and elevation. While important, aspect and elevation are more difficult to characterize across a large area and many model mines. Therefore, they were not included in this analysis." OSMRE's approach to addressing topography in the alternatives analysis is flawed. While it is indeed challenging to characterize the aspect and elevation of the land surface over a large area, GIS mapping technologies and portable imagery (including satellite imagery) has largely solved the challenge of capturing physical features over large land areas. In fact, it would appear that OSMRE will require mine operators and permit applicants to accomplish the very tasks that OSMRE claims were not done for the DEIS. The contradiction between what OSMRE will require from the mining industry after implementation of the Proposed SPR, and the methods OSMRE was willing to undertake in the DEIS are strikingly different.	potential impacts of the Alternatives on pre and post mining topography was conducted for relevant model mines in order to gain a general understanding of the likely benefits that may accrue. However, it is not possible to forecast the specific pre- and post mining slopes for all future mining operations across the U.S. Engineering would be conducted on a site-specific basis.
OSM-2010-0021-0696	Murray Energy Corporation	Action Alternatives and Potential Effects on Socioeconomic Conditions, Section 4.3.1.2, p. 4-185OSMRE relies on studies that use hedonic pricing schemes to assess the impact of improved water quality on property values physically situated adjacent to bodies of water in established recreational areas. It is highly questionable whether the magnitude of improvements evidenced in the referenced studies is applicable in mining regions. OSMRE provides insufficient basis to determine if the magnitude of the Benefits of improved water quality on property values is over or underestimated.	Thank you for the comment. No change is required. The EIS analysis does not attempt to quantify potential changes in property value associated with improved water quality because such an analysis would require a much greater degree of detail about mine locations and site-specific variables than is possible to achieve in a nationwide-scale analysis. Instead the EIS cites literature that relates property values to characteristics that lend to higher aesthetic value, such as improved water clarity. This degree of detail is appropriate given that the Proposed Action is unlikely to have substantial impacts to property values, positive or negative.
OSM-2010-0021-0696	Murray Energy Corporation	Land Use. Utilities, Infrastructure, Visual Resources, and NoiseSection 4.3.2, p. 4-242This section is meant to "describe the method for assessing the expected magnitude of impact of the Action Alternatives on these resources." OSMRE provides no discussion of how or why this group of disparate resources, with their very different attributes and socioeconomic and environmental aspects, can logically be	The analysis considers Land Use, Utilities, Infrastructure, Visual Resources and Noise in aggregate because associated impacts are primarily anticipated to result indirectly from changes in the volume of coal mined (as stated in EIS Section 4.3.2). Changes in the volume of coal mined as a result of the SPR are

BENEFITS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		assessed in aggregate. Further examination of the discussions of land use, utilities, infrastructure, visual resources, and noise within section 4.3.2.5 does not provide a clear presentation of the methodology actually used to assess the expected magnitude of impacts the Action Alternatives. The discussions for infrastructure, visual resources, and noise in particular include only observations or general assumptions, and no actual description of the methodology for assessing the impact and assigning the impact characterization labels defined in Table 4.0-1 (DEIS, at 4-8).	anticipated to be negative, i.e., less coal will be produced. This results in a reduction in adverse effects than would have occurred under the No Action Alternative. Additionally, the rationale for impact determinations by Action Alternative and coal region is presented in Table 4.3.2-3. Specific impacts on these resources are anticipated to range from negligible to moderately beneficial, depending on the region and alternative.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.3.2.1, p. 4-244 As noted in Sections 3.11.1 and 3.11.2.2 of the DEIS, visual resources are defined as including man-made components. This presents a conflict with the assumption made in Section 4.3.2.1 that "the public would prefer that natural pre-mining conditions be reproduced during reclamation." Actual stakeholder preferences are more likely to be highly variable depending on location and the mixture of residents and visitors in the shareholder population. OSMRE should not assume that reclamation to pre-mining conditions is the dominant stakeholder value in all locations affected by the Proposed Rule.	The text in 3.11.1 acknowledges that man-made features can be aesthetically appealing visual resources. For example man-made structures that are part of the historic context of a site would be visually appealing to most people, as would a mine site reclaimed to a ball field. The value of a visual resource is highly dependent on the individual perceiving it. However, for the purposes of assessing the impacts of a regulatory program such as SMCRA on a regional or nationwide basis it is reasonable to assume that the majority of people choosing to reside in the rural landscapes where coal mining is typically conducted would prefer reclamation to conditions that fit in with the surrounding natural landscape, over reclamation to site conditions that show a high degree of disturbance.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.3.2.5, p. 4-248, last paragraph "Stream definitions are central to the water quality protection objectives of the Action Alternatives. The No Action Alternative enumerates the elements used to define a general stream as well as an intermittent stream. Retention of the current stream definitions is anticipated to continue current mining effects on land use, utilities, infrastructure, visual resources, and noise. Changes in stream definitions associated with some of the Action Alternatives are expected to have an indirect effect on the respective resources." OSMRE does not measure or identify indirect effects as positive or negative. OSMRE, in fact,	OSMRE appreciates the commenter's concern related to the indirect effect associated with the Action Alternatives. Given the difficulty in quantifying indirect effects of the SPR, these impacts can and should only be discussed from a qualitative perspective. Several examples of indirect effects associated with various SPR elements are discussed in section 4.3.2.2.

BENEFITS			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		does not quantify any indirect effects of the Proposed Rule or the different action alternatives.	
OSM-2010-0021-0696	Murray Energy Corporation	OSMRE's approach to recognizing Benefits and impacts associated with mining is fundamentally flawed. The presumption that mining restoration by its nature will automatically reduce impacts to agriculture and residential/commercial development implies that mining itself must have a negative impact, regardless of whether the impact is demonstrable. The presumption of negative impacts is prevalent throughout the DEIS without supporting information. By this approach, OSMRE claims Benefits for mine restoration or changes to mining practices relative to impacts that OSMRE has failed to demonstrate or quantify. This grossly subjective approach is contrary to the fundamental practices prescribed in guidance for conducting an impact assessment (see e.g., Canter et al. 1996; U.S. EPA 2015).	Section 4.2.1.1 of the EIS summarizes some of the scientific literature that documents negative impacts of coal mining on water quality and biological resources downstream of mining activities (e.g., Dills and Rogers, 1970; Wangsness et al., 1981; Zuehls et al., 1984; Powell, 1988; Howard et al., 2001; Stauffer and Ferreri, 2002; Bryant et al., 2002; Hartman et al., 2005; Pond et al., 2008; U.S. EPA, 2011; Herlihy et al., 1990; Presser, 2013; Presser and Luoma, 2010). Impacts to these resources have been shown to persist despite current regulations (e.g., Paybins et al, 2000). Water quality can be improved through additional reclamation efforts such as establishment of riparian buffers which are articulated in the Alternatives. In addition, the Alternatives are anticipated to reduce the volume of coal that is mined, which would benefit water quality.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.3.3.1, p. 4-262 In this section, OSMRE includes predictions on how different reclamation techniques affect recreation opportunities such as hiking, wildlife viewing, hunting, and ATV riding. OSMRE claims the No Action Alternative will lead to a reduction in these opportunities, including a reduction in hunting opportunities because there will be less "wildlife," fewer visual attractions, and less desirable ground surfaces for recreation. The absence of objective information supporting these claims undermines the soundness of these assertions. OSMRE should clarify how it arrives at conclusions that the No Action Alternative is less desirable than other options.	Implementation of the SPR under any of the alternatives considered would bring about additional protection of the environment on which recreation activities depend. In comparison to the No Action alternative certain recreational activities would benefit from a healthier ecosystem, especially those activities that are associated with direct enjoyment of natural resources as a function of the productivity of the land and water. OSMRE acknowledges that the SPR is unlikely to positively impact every recreational activity, for example it is unlikely that ATV riding would be affected with the exception possibly of additional forested areas in which to ride.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.3.3.1, p. 4-263, third paragraph "While many people may choose to recreate on private resources, data on privately owned recreational resources are sparse and are not included in this analysis." The failure to properly address the private lands recreation issue due to alleged lack of data shows that OSMRE did not	OMSRE agrees that nature-based tourism, wildlife viewing, and hunting can contribute significantly to local and regional economies. Some of these activities occur on private lands. Elements of the SPR seek to reduce the short and long term adverse impacts of coal mining on

BENEFITS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		take a hard look in its analysis as required by NEPA. Many state wildlife agencies in coal-producing states collect very good data on hunter harvest of deer, elk, bears, and turkeys on public and private lands. These same state wildlife agencies have formal hunter access agreements with large corporate landowners in coal-producing counties. As coal production declines in some areas, counties and states are actively trying to find new economic activity and drivers. Many people believe that nature-based tourism, wildlife viewing, and hunting can help provide that economic stimulus.	the natural landscape. Thus, recreational opportunities on or near reclaimed mine lands could be enhanced following the SPR implementation, including on private lands. Unfortunately, the data on recreational visitation to private lands are inconsistent on a national scale, and do not provide sufficient data to understand the extent and quality of private land habitats and how these characteristics could be affected by the alternatives considered. The metrics captured in hunter harvest data (e.g. hunter success rates, days of effort per harvested animal, total days of effort, number of licenses sold) present a valuable snapshot of historic and current hunter activity. However this data provides no additional insight on expectations for future management of private lands or expectations of future hunter harvests with or without implementation of any particular alternative. Management of public lands is more predictable and subject to overarching goals that are established under public review. Nonetheless, following the public comment period, OSMRE has revised the recreation analysis to incorporate a data set that is inclusive of protected private lands in addition to public lands. In addition, we have reframed the analysis to focus on presenting the total state and regional levels of fishing, hunting, and wildlife viewing activity rather than attempting to allocate it to the study area.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.3.3.1, p. 4-264 OSMRE uses the metric of public lands acreage as the basis for wildlife recreation. One major flaw in this approach and analysis is that in the eastern U.S., no mining occurs on public land, while most mining in the western U.S. is on public land. Thus, any assumptions based on this metric will lead to an inaccurate conclusion.	OSMRE agrees that using public lands as a proxy for understanding recreation levels is imperfect. Following the public comment period, OSMRE has revised the recreation analysis to incorporate a data set that is inclusive of protected private lands in addition to public lands. In addition, we have reframed the analysis to focus on presenting the total state and regional levels of fishing, hunting, and wildlife viewing activity rather than attempting

BENEFITS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
			to allocate it to the study area.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.3.3.2, p. 4-276, second paragraph "The absence of a reforestation requirement in the No Action Alternative may be the most pronounced of these conditions in contributing to adverse impacts on recreational opportunities." Whether reforestation is advisable for a particular mine site depends on the habitat characteristics of the landscape surrounding the mine site and which wildlife species are the focus for habitat restoration and for providing recreational opportunities. OSMRE has unilaterally determined that only forest-dependent species are valuable for recreation, while neglecting grassland-related species and habitat.	No change is required. The discussion that the comment is referring to provides no absolutes on the value of reforested areas for recreation versus previously forested areas that have been converted to some other land use that is non-forested. The discussion qualifies the statements presented such that it is clear that other variables may affect the degree of impact on recreation. See the discussion in Chapter 4 that acknowledges that changes in vegetation and habitats may actually facilitate the return of a species that is appealing for hunting and viewing.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.3.3.3, pp. 4-278 to 4-279 "In the short term, reducing the availability of habitat through mining activities may result in a greater concentration of wildlife in adjacent hunting areas. The scale of the anthropogenic disruption associated with a coal mine, however, would also be expected to disrupt nearby wildlife, leading to a longer-term reduction in the abundance of animals for hunting. This is especially true for surface mines, which generally pose a greater disruption to terrestrial habitat." Hunting statistics in states where mining occurs, and particularly over the past 30 years in Appalachia, indicate hunter harvest of deer and other wildlife game species have increased substantially (see for example Campbell et al. 2005, Larkin et al 2003). OSMRE fails to reconcile available state data and published studies with claims that reclamation has failed to attract and support wildlife.	We have reframed the analysis to focus on presenting the total state and regional levels of fishing, hunting, and wildlife viewing activity. Please refer to Master Response on Reforestation for additional details.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.3.3.3, p. 4-279 By its own admission, and fatally, OSMRE offers no substantive information upon which to make judgments about wildlife populations and recreation (hunting) associated with each of the DEIS alternatives, and thus cannot provide a valid analysis. The absence of objective information supporting OSMRE's claims undermines the soundness of its assertions. OSMRE must clarify how it arrives at conclusions that the No Action Alternative is less desirable than other options.	Please refer to Master Response on Reforestation.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.5.3.4, pp. 4-357 to 4-358 Beneficial implications are claimed for air quality due to	Although the EIS discusses air quality Benefits that may accrue through increased carbon

BENEFITS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		the potential to increase carbon sequestration due to reforestation and riparian corridor requirements of all action alternatives except for Alternative 9. This seems unlikely to make any measurable difference in the amount of carbon in the atmosphere.	sequestration associated with increased reforestation efforts, these are not quantified in the analysis. The FEIS quantifies potential air quality Benefits associated with the anticipated reduction in coal production and subsequent combustion of an estimated 0.2% of projected coal production.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.5.3.8, p. 4-361 [A]ll Action Alternatives are expected to have Negligible impacts on archaeology, paleontology, and cultural resources on both the regional and national level. In reality, mining projects often bring to light such resources through the mandated studies which must be conducted prior to any mining-related surface disturbance in areas that may contain such resources. Without mining, many of these resources would likely not be discovered, studied, and catalogued, and many would be lost to the ravages of time prior to knowledgeable experts having the chance to observe them.	The commenter is correct in that mining projects often bring to light archaeological, paleontological, or cultural resources through the mandated studies which must be conducted prior to any mining-related surface disturbance in areas that may contain such resources. Because the SPR is expected to have a small impact on coal production, there will likely not be a realizable benefit to archaeology, paleontology, and cultural resources relative to the current practices of the No Action Alternative. Therefore, Benefits to this resource are expected to be small or Negligible.
OSM-2010-0021-0068	Earthjustice	OSMRE admits that "the Action Alternatives could influence coal use at power plants and thereby affect the emission of greenhouse gases and associated social costs." DEIS 4 175. But OSMRE declines to estimate or quantify the impacts, claiming that the task would be "complex." Id. OSMRE's failure even to attempt to characterize the differential climate impacts of its alternatives violates NEPA.	Thank you for your comment. In response, an analysis of the potential impacts of the SPR on greenhouse gas emissions and the associated social costs of carbon is now included in Chapter 7 of the Final RIA and Chapter 4 of the FEIS.
OSM-2010-0021-0068	Earthjustice	As part of its consideration of a rule that will govern the circumstances under which hundreds of millions of tons of coal may be mined for combustion, and certainly before rejecting more environmentally protective alternatives, OSMRE must inform the public and decisionmakers of the dramatic reductions in greenhouse gases that are required to avert global catastrophe.	Thank you for your comment. In response, an analysis of the potential impacts of the SPR on greenhouse gas emissions and the associated social costs of carbon is now included in Chapter 7 of the Final RIA and Chapter 4 of the FEIS.
OSM-2010-0021-0696	Murray Energy Corporation	Air quality also will likely be degraded as a result of additional use of light-duty and heavy-duty equipment and the resulting increase in exhaust and fugitive dust.	In Chapter 7 of the Final RIA and Chapter 4 of the FEIS of the EIS, OSMRE recognizes that in addition to the air quality Benefits associated with reduced mining activities, there may some increase in greenhouse gas emissions from exhaust and fugitive dust from the use of light-duty and heavy-duty equipment used in mitigation.

COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
OSM-2010-0021-0696	Murray Energy Corporation	Scope of the Proposed Stream Protection Rule Section ES.3, p. ES-7 "First, while ephemeral streams derive their flow from surface runoff from precipitation events, perennial and intermittent streams derive their flow from both groundwater discharges and surface runoff from precipitation events. Therefore, there is a need to clearly define the point at which adverse mining-related impacts on both groundwater and surface water reach an unacceptable level; that is, the point at which adverse impacts from mining cause material damage to the hydrologic balance outside the permit area." This rationale is not consistent and is an indication of the difficulties posed in trying to provide a purported "scientific rationale" for the Proposed Rule. While the statement regarding sources of water flow in ephemeral, intermittent, and perennial streams is accurate, it is irrelevant to the "need to clearly define . . . adverse mining-related impacts." Quantifiable metrics related to substantive adverse impacts on the hydrologic balance with respect to surface waters not being able to support pre-mining uses are needed, but the source of flow in the various stream types is irrelevant to this need. The rationale is additionally flawed given that, except for potential subsidence in shallow mining systems, underground mining would have no impact on ephemeral streams.	The text has been simplified to address the comment and remove the inconsistency (see Executive Summary).
OSM-2010-0021-0696	Murray Energy Corporation	OSRME's monitoring requirements appear to target at least tier 2 surface water conditions, which in some cases are not compatible with prior baseline conditions or achievable for ephemeral streams and many intermittent streams. Water quality and baseline conditions are established early in the mine permit process, wherein NPDES permits must go through an antidegradation analysis, either through an individual permit analysis or a general permit analysis. The DEIS ignores this procedure and would align restoration goals and benchmarks with the broad tier 2 "high quality" criteria, rather than actual, site-specific baseline conditions.	See the final rule preamble for information on the intent of the proposed monitoring requirements as well as the incorporation of anti-degradation concepts into the definition of material damage to the hydrologic balance outside the permit area.
OSM-2010-0021-0696	Murray Energy Corporation	Adding monitoring requirements for major ions, ammonia, nitrogen and other compounds will not improve water quality as claimed in the DEIS.	In the final version of the Preferred Alternative we have deleted the six parameters (ammonia, arsenic, cadmium, copper, nitrogen, zinc) that we had added the Preferred Alternative at U.S.

BENEFITS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
			EPA's request. Our research found that those parameters have little or no nexus to coal mining. Instead, they appear to relate to placement of coal combustion residues in mines, which is the subject of a separate rulemaking.
OSM-2010-0021-0696	Murray Energy Corporation	Section ES.5, p. ES-22, first bullet at top "The total volume of flow during any season of the year would not vary; i.e., the seasonal flow regime would not change and there would be no increase in potential damage from flooding." The above statement is nonsensical and requires clarification.	Edits made to clarify that the text was referring to no change from premining conditions and not between seasons of the year. See Executive Summary.
OSM-2010-0021-0696	Murray Energy Corporation	Section 1.0.3.1, p. 1-7 U.S. EPA, Mountaintop Mining/Valley Fills in Appalachia, Draft Programmatic Environmental Impact Statement (MTM-VF DPEIS), U.S. EPA 9-03-R- 00013, U.S. EPA Region 3, June 2003 and Final Programmatic Environmental Impact Statement (MTM-VF FPEIS), October 2005.At the time of its release, experts raised several concerns, criticisms, and deficiencies regarding this document and its supporting analyses.....Regulators and the regulated community still disagree concerning the severity of impairment from mining, as demonstrated by a new study, commissioned by OSMRE and U.S. EPA, by Pond et al. (2014). Similarly, Palmer and Bernhardt (2009) observed similar unresolved issues regarding impacts and mitigation options in U.S. EPA's 2005 programmatic EIS. OSMRE has not corrected these issues and deficiencies, nor has OSMRE addressed these criticisms in the DEIS. Therefore, OSMRE's reliance on this debated and potentially flawed	No change required to the text or the analysis. The use of the 2005 U.S.. EPA, Mountaintop Mining/Valley Fills in Appalachia, Draft Programmatic Environmental Impact Statement (MTM-VF DPEIS), U.S. EPA 9-03-R- 00013, is very limited. In regard to the topic of downstream effects the 2015 OSMRE DEIS for the SPR cites the 2005 MTM- VF DPEIS one time only (see page 4-90 of the DEIS), within a sentence describing the role of macroinvertebrates as a food source and as indicators of stream degradation. The section provides numerous other scientific studies to discuss the topics of the effects of water quality degradation on aquatic biota as a measure of the severity of degradation. See the discussion of "Documented Impacts Related to Activities in or Near Streams" within Section 4.2.2.1.
OSM-2010-0021-0696	Murray Energy Corporation	Further, the DEIS and Proposed Rule fail to capture the scientific data on the success associated with stream and environmental protection and reclamation.	Thank you for your comment. OSMRE has presented the state of the known science regarding stream restoration successes and challenges in the DEIS and the preamble to the proposed rule. Additionally OSMRE reviewed the table of studies provided in conjunction with these comments, titled "Literature Discussing Positive Impacts of Mining, Which OSMRE Failed to Cite in the DEIS." While two of the more than 50 sources listed in the appendix provide some indication of the positive effects

BENEFITS			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
			on the biological community of treating AMD, and two sources document recovery of stream flow and topography, the references provided largely communicate changes and updates to existing practices.
OSM-2010-0021-0696	Murray Energy Corporation	Need for the Regulatory ImprovementsSection 1.1.1, p. 1-12OSMRE also does not accurately or fairly portray the mining industry's approach to stream reconstruction. According to OSMRE, stream reconstruction has been historically focused on minimizing channel erosion and sediment loading, with little regard given to enhancement of fish, wildlife, and related environmental values. However, the restoration of streams to sustainable recreational and ecological condition is a stated goal of reclamation work in the mining sector (see www.NMA.org).	While stream restoration to sustainable recreational and ecological function may be a stated goal of the National Mining Association, studies have documented that mining impacts to streams outweigh mitigation (see: Palmer and Hondula, 2010, and Bernhardt and Palmer, 2011).
OSM-2010-0021-0696	Murray Energy Corporation	Section 1.1.2, p. 1-13 "As discussed previously, studies indicate that environmental degradation is still occurring despite the current requirements within the implementing regulations of SMCRA." Pfannenstiel and Wendt (2002) cite 15 scientific studies published since the implementation of SMCRA that reflect advancements from research, application of new and improved technologies, mine-specific experience, and innovation that have reduced negative impacts on streams, fish, and wildlife. The mining industry's success is evident in the tens of thousands of stable and productive reclaimed acres where postmine land uses have already been implemented. In fact, Angel et al. (2005) observed in a December 2005 Forest Reclamation Advisory prepared by the ARRI: "SMCRA improved the surface mine landforms by increasing stability, improving water quality, and enhancing human safety in the Appalachian region, compared to the results of pre-SMCRA mining." See also Appendix A, attached (providing a table of literature discussing the positive impacts of mining, which OSMRE failed to cite in the DEIS).	The text in question is not claiming that there have not been advances made in reclamation science. Further, OSMRE acknowledges the progress made toward better reclamation practices since the inception of SMCRA. However, the commenter is stating that there are no disturbances to land and resources given improvements in technology, which is not the case. A simple analysis of the references provided in Appendix A reveals that impacts related to mining still occur despite the current state of reclamation science.
OSM-2010-0021-0696	Murray Energy Corporation	Need to Apply Current Information, Technology, and MethodsSection 1.1.4, p. 1-16"OSMRE experience over the past thirty years indicates that extensive herbaceous ground cover on reclaimed areas can inhibit the establishment and growth of trees and shrubs. The dense herbaceous ground	The text is clear and is not oversimplified. The text acknowledges the use of these ground covers for the control of erosion and in no way discounts the importance of erosion control, but continues on in the segment captured in the

BENEFITS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		covers often used to control erosion compete with newly planted trees and tree seedlings for soil nutrients, water, and sunlight, and provide habitat for rodents and other animals that damage tree seedlings and young trees."OSMRE grossly over simplifies this issue and mischaracterizes an important consideration in reclamation planning. While herbaceous ground cover can inhibit the growth of trees and shrubs in some landscapes and ecoregions, the trade-off between ground vegetation that secures soil in place and minimizes soil runoff in the short-term is always examined relative to the long-term value of promoting a landscape of trees and shrubs.	comment to explain that the choice of ground covers is important to prevent the ground covers from out-competing other desired vegetation.
OSM-2010-0021-0696	Murray Energy Corporation	Activities in or Near Streams Section 2.4.4.2, p. 2-25 "Alternative 4 defines perennial, intermittent, and ephemeral streams in terms of flow regime, channel and substrate characteristics, and the biological community, if any, found in the stream. The definition of an intermittent stream would no longer include the one-square-mile watershed criterion." OSMRE fails to explain how the "flow regime, channel and substrate characteristics, and the biological community" would be used to differentiate between perennial, intermittent, and ephemeral streams.	See the preamble for section 701.5 of the rule for discussion of the definitions of streams as ephemeral, intermittent or perennial.
OSM-2010-0021-0696	Murray Energy Corporation	Activities in or Near StreamsSection 2.4.7.2, p. 2-32, second paragraph"Same as the No Action Alternative, except that Alternative 7 would remove the one square-mile criterion in the existing definition of an intermittent stream. Alternative 7 would require coordination with the Clean Water Act authority on defining stream flow condition. Both the permit applicant and the regulatory authority must seek input from the Clean Water Act Authority for all new applications, and incorporate where applicable all CWA authority concerns and criteria."Although the removal of the one-square-mile criterion from the definition of an intermittent stream is reasonable, stream types should be tied to flow source and the presence/absence of beneficial uses, as defined under the CWA. OSMRE should refine these definitions.	See the preamble for section 701.5 of the rule for discussion of the definitions of streams as ephemeral, intermittent or perennial.
OSM-2010-0021-0696	Murray Energy Corporation	Section 2.4.8.2, p. 2-34, last paragraph "Alternative 8 (Preferred) would redefine "perennial stream " in a manner that is substantively identical to the manner	Definitions for each stream type under the final version of the Preferred Alternative have been added. See Section 2.4.8.2 of the FEIS.

BENEFITS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		in which the USACE defines that term in Part F of the 2012 reissuance of the nationwide permits under section 404 of the Clean Water Act. See 77 FR 10184, 10288 (Feb. 21, 2012[).]" The cited document defines perennial stream: "A perennial stream has flowing water year-round during a typical year. The water table is located above the stream bed for most of the year. Groundwater is the primary source of water for stream flow. Runoff from rainfall is a supplemental source of water for stream flow." The DEIS and Proposed Rule should include the language of this definition directly and not require cross-reference to another document.	
OSM-2010-0021-0696	Murray Energy Corporation	The DEIS suggests that intermittent and ephemeral streams would not be defined. Because the allowable actions in and around streams also related to intermittent streams, OSMRE should provide a definition for intermittent. The definitions in 77 Fed. Reg. 10,184, 10,288 should be included in the definitions for Alternative 8.	For additional clarity the FEIS text has been revised to include the definitions for ephemeral and intermittent streams as included within the final rule. See Section 2.4.8.2.
OSM-2010-0021-0696	Murray Energy Corporation	Groundwater Usage OverviewSection 3.5.2.2, p. 3-131The use of groundwater as a beneficial resource is not disputed. The types of beneficial uses, however, can vary among states. OSMRE appears to suggest that all groundwater provides all of the listed beneficial uses. This is simply not the case. The availability of groundwater for a particular beneficial use, such as drinking, largely depends on whether the groundwater meets the applicable state and/or local water quality and water quantity standards....OSMRE must show flexibility in its definition of beneficial use relative to the state and region in which the mine is operating.	The text is merely listing groundwater beneficial uses and not implying that each use is relevant to all areas; not every area for example is urban.
OSM-2010-0021-0696	Murray Energy Corporation	233. Federally Protected and Regulated Species Section 3.8.2.2, p. 3-246 References to Appendix F Critical Habitat Overlap with Coal Regions are inadequate for identifying species' critical habitat for a specific region because the appendix is a summary for all regions collectively. OSMRE should separate the appendix into listed species by cover type by region.	The level of detail in the DEIS was sufficient but has been updated. The DEIS analyzed regional distributions of critical habitat, as well as the distribution of forest cover. Additional detail on species and habitats by region are contained within the Biological Assessment and Biological Opinion for the Stream Protection Rule.
OSM-2010-0021-0696	Murray Energy Corporation	Federally Protected and Regulated Species Section 3.8.2.2, p. 3-246 In fact, abandoned (or exhausted) coal mines may potentially mitigate impacts by providing new (or	The comment is accurate but requires no change to the text of the EIS.

BENEFITS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		additional) winter or roosting habitat for a variety of bat species, including Indiana bats (U.S. FWS et al., 2009).	
OSM-2010-0021-0696	Murray Energy Corporation	*Section 4.2.2.2, p. 4-98* *The loss of forest and other habitat at mine locations under the No Action Alternative has a direct adverse effect on wildlife by reducing the total quantity of available habitat, as well as an indirect effect through habitat fragmentation. Impaired habitat conditions adversely affect the ability of a coal mining region to support particular species and may in turn negatively affect wildlife-related recreational activities, including hunting and wildlife viewing (as described in Section 4.3.3).* This statement is incorrect. Without the surface mining and reclamation that has occurred since 1977, many wildlife populations in Appalachia would be much lower than they are now.	The commenter is implying that mining and reclamation somehow provides more wildlife Benefits than if no mining has occurred at all. Prior to coal mining, fauna such as elk, white-tailed deer, and wild turkey were prolific in natural habitat mosaics. The use of early successional habitat by the cited fauna is simply an adaptation to fragmented habitat.
OSM-2010-0021-0696	Murray Energy Corporation	The Action Alternatives contain elements that would improve the quality and/or quantity of habitat within a permit boundary, increasing wildlife species richness and abundance within the permit boundary and on adjacent lands. These Benefits to wildlife species may improve wildlife related recreational experiences in the coal regions, as described in Section 4.3.3. It is unclear why OSMRE asserts authority for determining wildlife conservation objectives on public and privately owned lands. When it pertains to private land, the habitat type and vegetation on a mine site after the life of the mine permit and reclamation bond is beyond the authority and responsibilities of OSMRE and the states. The rights of the private property owner must be protected and respected.	No change is required in response to this comment. Nothing described in the EIS or the rule would alter private landowner rights after the release of the bond.
OSM-2010-0021-0696	Murray Energy Corporation	*Section 4.2.4, pp. 4-156 to 4-157* *OSMRE is limited in its ability to regulate air quality. Air emissions permits for coal mines fall under the authority of the Clean Air Act (CAA) and are not issued under SMCRA. The decision discussed in In re Permanent Surface Min. Regulation Litig. I, Round II, 1980 U.S. Dist. LEXIS 17660 at *43-44 (D.D.C., May 16, 1980), 19 Env't Rep. Cas. (BNA) 1477, clarifies that OSMRE does not have jurisdiction over industrial emissions, and that its jurisdiction is limited to air pollution attendant to wind and water erosion (e.g., exposing soil to wind causing particulates to become airborne). The decision clarifies that all other mining-*	OMSRE does not regulate air emissions, nor does it propose to do so under the SPR. However, NEPA analysis is not limited to assessment of impacts to resources that are regulated by the issuing agency. As stated in the Section 4.2.4 of the EIS, the discussion examines air quality as a resource within the human environment, focusing on the specific components that coal mining operations can influence.

BENEFITS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		related emissions are generally regulated under the CAA and not SMCRA. The following discussion examines air quality as a resource within the human environment, focusing on the specific components that coal mining operations can influence, and does not limit the discussion to what OSMRE is specifically authorized to regulate (i.e., erosion related air pollution). This provides the required basis (40 CFR 1502.16) for a scientific and analytic comparison between the Alternatives. After specifically describing the agency's limited authority under SMCRA to regulate air quality, OSMRE nonetheless continues on to discuss emissions as part of the analytic comparison between alternatives, rather than limiting its discussion to what OSMRE is authorized to regulate.	
OSM-2010-0021-0696	Murray Energy Corporation	*Section 4.2.4.3, p. 4-167 U.S. EPA estimates that methane emissions from surface coal mining are twice that of the in situ methane content of the mined coal.* In discussing the amount of methane (a greenhouse gas) that is released by surface mining, OSMRE suggests that all of the in situ methane will be released. This has to be a rarely reached upper bound, as some of the methane will ship with the coal to provide energy when it is burned.	The analysis of GHG emissions in the FEIS is updated in Section 4.2.4. The estimated change in methane emissions reflect fugitive emissions from field production of coal (and substitute natural gas), emissions from vehicle and equipment use, and transportation and storage. The emissions profiles of these activities are from the U.S. EPA's *2016 Inventory of U.S. Greenhouse Gas Emissions and Sinks*.
OSM-2010-0021-0696	Murray Energy Corporation	*Section 4.2.4.4, p. 4-171* *None of the rule elements directly reduces or changes blasting practices.* While none of the rule directly relates to changes in blasting practices, changes to blasting practices may occur due to indirect pressure and future fume regulations.	Thank you for the comment. The SPR is not materially modifying blasting regulations.
OSM-2010-0021-0696	Murray Energy Corporation	*Section 4.3.2.5, p. 4-250, first paragraph* *Under the No Action Alternative, the most visible impact of AOC variances would be the continued limited creation of flat or gently rolling terrain in areas that previously contained primarily steep slopes. More moderate slopes also may reduce surface runoff because of higher infiltration rates. Alternative 2 would prohibit all AOC variances and would likely require amendment of SMCRA. Alternatives 3, 4, 5, and 8 (Preferred) likely would result in the approval of fewer operations with AOC variances. Therefore, Alternatives 2, 3, 4, 5, and 8 (Preferred) should*	It is true that the Preferred Alternative has the same definition of AOC as the No Action Alternative, and that the Preferred Alternative allows mountaintop removal mining operations and AOC variances for steep-slope mining operations under conditions generally similar to those of the No Action Alternative. However, the Preferred Alternative requires permittees to comply with additional requirements that include using native species, reducing the amount of exposed excess spoil fills, and

BENEFITS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		result in fewer permanent visual effects than would be expected under the No Action Alternative. Alternatives 6, 7, and 9 are similar to the No Action Alternative in terms of AOC variances and, thus, would have similar impacts. OSMRE provides no evidence that the Preferred Alternative will result in anything different from the current regulations with respect to AOC variances.	ensuring that no damage is done to natural watercourses within the watershed. OSMRE's analysis reflects the differences between the No Action Alternative and the Preferred Alternative. Mining results in reduced vegetation, altered topography, establishment of non-native species, and greatly disturbed landscapes overall. These alterations do in fact have the potential to impact visual resources.
OSM-2010-0021-0696	Murray Energy Corporation	*Section 4.3.3.1, p. 4-268, first bullet* *Private lands supporting mining currently or in the future may also provide recreational opportunities. While not accounted for in the analysis of recreational land, recreation on private land could be affected by the Action Alternatives.* In the coal-producing counties in Central Appalachia, the best hunting for deer, turkeys, elk, rabbits, quail, doves, and even waterfowl is generally on or adjacent to reclaimed mine sites. OSMRE states that "recreation on private land could be affected," but it will no doubt be affected, negatively, by the action alternatives.	The aspects of the SPR that could impact hunting are 1) revegetation, topsoil management, and reforestation and 2) wildlife protection and enhancement. The commenter is assuming that more stringent proposed revegetation and reforestation requirements will negatively affect recreational activities, particularly hunting. However, the proposed revegetation requirements would re-establish native vegetation, which supports local species targeted for hunting. Reforestation can take a decade or more to occur, but mountain forest landscapes are highly preferred for many recreational activities including hiking, hunting, wildlife viewing, and others. While it is uncertain that there would be an adverse impact to recreational hunting, any short-term effect to hunting would be minimal relative to the long-term Benefits to many recreational activities, including hunting, that could occur by returning the landscape to its natural state with respect to vegetation.
OSM-2010-0021-0696	Murray Energy Corporation	Analytic Methods for Surface Water Resources Section 4.2.1.3, pp. 4-66 to 4-67OSMRE's assumptions regarding the geographic extent of downstream mining effects is based on one study conducted in one region of the country, and is not representative of conditions in other coal mining regions. OSMRE fails to provide supporting data to assert that every mining operation across the U.S. behaves similarly.	Please refer to Master Response on Water Quality Benefits for a discussion of the methodology used to calculate benefits to downstream water quality. This discussion clarifies the methodology used to account for regional differences.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.1.3, p. 4-67 In absence of additional studies estimating the geographic extent of downstream effects from mining in other coal	Section 4.2.1 has been clarified to better articulate assumptions in the EIS. Please also refer to Master Response on Water Quality

BENEFITS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		mining regions, OSMRE applies findings from Appalachia to other coalmining regions. Consequently, it is difficult to determine if OSMRE's analysis over- or underestimates affected stream length. OSMRE's analysis assumes that adverse effects on water quality persist 6.2 miles downstream of mines for streams that cross the disturbed mine site. Despite acknowledging that the assumption for the analysis can vary widely, OSMRE inexplicably relies upon the results to draw conclusions about downstream effects.	Benefits for a discussion of the methodology used in the FEIS, and the particular application of the study from which the 6.2 mile assumption is based. The analysis therefore estimates the benefits of the rule using the 6.2-mile downstream distance as an indicator and planning tool to allow comparison between alternatives.
OSM-2010-0021-0696	Murray Energy Corporation	Results of Quantitative Analysis of Surface Water ImpactsSection 4.2.1.4, pp. 4-70 to 4-71, fourth bullet"The vast majority of preserved stream miles occur in Appalachia, the region anticipated to experience the greatest reduction in surface coal mining activity under the Action Alternatives."OSMRE's conclusion is not surprising because the vast majority of the analysis was based on Appalachian Basin data. The results have little relevance to coal mining activity in regions other than the Appalachian Basin.	Please refer to Master Responses on Model Mines Analysis and Water Quality Benefits.
OSM-2010-0021-0696	Murray Energy Corporation	Results of Quantitative Analysis of Surface Water Impacts Section 4.2.1.4, pp. 4-71 to 4-72, third bullet The 2005 Mountaintop Mining EIS (U.S. EPA, 2005) also included a study that estimated impacts of mountaintop mining and valley fills between 1992 and 2002 of 1,200 stream miles (equating to approximately 110 per year), out of 58,998 streams in the study area. As with the previous study, this study also used GIS modeling of "synthetic streams " (in that they were not generated from existing maps, but instead were created by assuming that 30-acre areas generate a stream, which was not ground trothed) to estimate potential impacts. The studies referenced by OSMRE are two to three or more decades old. OSMRE fails to rely on recent information to assess the impact of the Proposed Rule, which it must do as a necessary predicate for demonstrating the necessity for the Proposed SPR.	Please refer to Master Response on Water Quality Benefits and Model Mines Analysis.
OSM-2010-0021-0696	Murray Energy Corporation	Potential Minimization and Mitigation Measures Section 4.2.1.6, p. 4-83 It remains unclear how OSMRE's evaluation demonstrates the magnitude to which groundwater quality will be improved by the Proposed Rule.	Direct Benefits to groundwater were not directly quantified, but related to the demand for groundwater resources in mining regions. The text has been reworded to remove quantitative connotation.
OSM-2010-0021-0696	Murray Energy	Effects of the Current Regulatory Environment (the No	The section of the EIS cited by the commenter

COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
	Corporation	Action Alternative) Section 4.2.2.1, p. 4-88 "Adverse impacts on ecological communities continue to occur in coal mining regions, as documented in studies discussed below. Many of the available studies were conducted in the Appalachian Basin region (e.g., U.S. EPA et al, 2003; Pond et al, 2008; Palmer et al, 2010; Woody et al., 2010; Bernhardt et al., 2012; Pond, 2012; Pond et al, 2014). However, studies are available from other coal-producing areas, e.g., Big Black River tributaries in Mississippi (Rohasliney and Jackson, 2009), Hocking River drainage basin in southeastern Ohio (Verb and Vis, 2000), and streams in British Columbia (Harding et al., 2005). Two other states, Colorado and Indiana, have studies reporting directly on stream effects of coal mining; however, these studies were performed before 1983 (Canton and Ward, 1981; and Wangsness, 1982) and may not be representative of impacts that are occurring under existing regulations." The studies selected and presented throughout the document use biased information with limited variables to examine the effects of coal mining.	presents a summary of available scientific literature in which impacts of coal mining under the current on ecological communities have been examined and documented. This literature has been refined in the FEIS. The commenter does not explain why they allege that the information is biased or suggest additional studies for OSMRE to consider. OSMRE evaluated the available science, using the agency's scientific discretion to determine how to evaluate the available science. There is no benchmark regarding a specific number of variables that should be reported on to sufficiently address ecological impacts associated with coal mining operations.
OSM-2010-0021-0696	Murray Energy Corporation	Effects of the Current Regulatory Environment (the No Action Alternative) Section 4.2.2.1, pp. 4-93 to 4-94 "The requirements of 30 CFR 816.43 provide for restoration of stream flow and riparian vegetation, but do not require restoration of biological communities. Studies have shown that it can be difficult to restore biological characteristics in an engineered stream channel (e.g., Northington et al, 2011). In another example, Fritz, et al. (2010) compared ephemeral, intermittent, and perennial streams at reclaimed valley fills to naturally occurring forested streams. They detected significant differences in leaf litter breakdown (a critical process that provides nutrients and energy to the stream ecosystem beyond the mine site) and invertebrate assemblage when comparing valley fill reclaimed (constructed) perennial and intermittent streams to naturally occurring forested perennial and intermittent streams. The study also detected significant differences in coarse benthic organic matter and invertebrate assemblage (important parts of the foundation to the stream ecosystem) between reclaimed and natural ephemeral streams." OSMRE neglects to state that the streams studied on mine	No change required. The text does not imply that leaf litter breakdown occurs only within the riparian zone. This important nutrient regeneration process is also facilitated by detritivores in the waterway itself.

BENEFITS			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		sites do not have riparian zones, and therefore will be unable to provide the leaf litter breakdown desired.	
OSM-2010-0021-0696	Murray Energy Corporation	Effects of the Current Regulatory Environment (the No Action Alternative) -Documented Impacts on Forest and Other EcosystemsSection 4.2.2.1, pp. 4-94 to 4-96OSMRE provides only general statements regarding the documented impacts, and most of the citations used are not from any studies or research related to mining. For example, Vitousek et al. (1997) was a paper published in Science titled "Human Domination of Earth's Ecosystems." Rosenzweig (1995) is cited in the section regarding habitat fragmentation caused by mining. This was not a paper or research report regarding mining. It is a conservation biology textbook titled Species Diversity in Space and Time. The next citation is from a book titled, Tropical Forest Remnants: Ecology, Conservation, and Management of Fragmented Communities. The citation from Crooks, et al. (2001) was a research report from a study done on birds in habitat fragmented by urban development in southern California. The citation from Steven and Husband (1998) is from a paper titled "Influence of Edge on Small Mammals: Evidence from Brazilian Atlantic Forest Fragments." The citation from Hobbs and Humphries (1995) is from a paper that did not relate to mining. The citation from Richardson et al. (2000) is from a paper that explains the authors' proposal of new definitions for the words used in describing invasive species. The authors are from South Africa, the Czech Republic, Australia, New Zealand, and California.	NEPA requires a description of the environment of the areas to be affected or created by the alternatives under consideration. 40 CFR 1502.15. The alternatives under consideration would affect wetlands; the purpose of this section therefore is to provide a baseline description of wetlands including the current status of these resources and the contributing factors to the existing status. The impacts of mining under the alternatives being considered are addressed in Chapter 4 within the Environmental consequences section, as required by 40 CFR 1502.16.
OSM-2010-0021-0696	Murray Energy Corporation	OSMRE had six years to complete a thorough literature review on the impacts of surface mining as it pertains to fish and wildlife, and yet this section of the DEIS completely misses the mark in drawing the connection between mining and impacts on forests and other ecosystems. In 2011, the Appalachian Wildlife Foundation (AWF) commissioned Dr. David Beuhler from the University of Tennessee to conduct and write up a review of all the literature that could be found about coal mining and wildlife. The review was completed in 2012 and has been posted on AWF's website, at www.appalachianwildlife.com/news.html, since then. A short excerpt from that review demonstrates the breadth of literature available to OSMRE for review: "The literature review yielded almost 300 articles, reports, dissertations,	OSMRE appreciates the recommendation to review and include the Buehler and Percy literature synthesis of the effects of surface mining on wildlife. This literature review, sponsored by the AWF and others, was thorough and exhaustive. However, despite this extensive literature search, the authors note that very little information exists on the direct effects of coal mining on wildlife. The majority of the studies that literature review returned were "focused simply on documenting the numerical response of species in question on the mine site during some time period post-reclamation." Further, while many of these studies may note

BENEFITS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		theses, extension bulletins, and other documents of interest (Table 1). There has been a considerable amount of work on many species of wildlife, with the majority (74 citations) of the studies being on birds. In addition, there has been a lot of research (93 articles) on reclamation practices."	quantitative use of reclamation sites by wildlife, the reports are generally qualitative in nature. While the statement early in the text cited in the comment indicates a robust literature regarding the impact of coal mining on wildlife, a more thorough review of the document clearly demonstrates that very little information exists describing or quantifying these types of impacts.
OSM-2010-0021-0696	Murray Energy Corporation	Effects of the Current Regulatory Environment (the No Action Alternative) Section 4.2.2.1, p. 4-95, first paragraph It is unlikely that an entire species would be located only where a mining operation is to occur, such that the mining would be the sole cause of any impacts to the species and could potentially contribute to species extinction. And if that were the case, current regulations would sufficiently protect the species and prevent the mining operation from having such a negative impact.	In response to this comment, additional discussion was added to Section 4.2.2.1 describing that it is generally a combination of factors that leads to a species population decline or extinction. However, coal mining is one threat for multiple aquatic and terrestrial species that has contributed to declining populations. In addition, while the federal listing status of some species would trigger requirements for coal mines to avoid adverse effects (e.g., ESA section 7 consultation) absent the SPR, managing coal mines to reduce adverse water quality impacts and forest habitat loss will reduce the potential for coal mining to be a contributing factor in species and habitat decline. Furthermore, the guidance provided by the SPR regarding water quality management and forest reclamation informs coal mining interests how to best manage mine sites to avoid the potential for adverse impacts on listed species.
OSM-2010-0021-0696	Murray Energy Corporation	Impacts of the No Action Alternative on Water Resources: Chemical Effects on Surface Waters Section 4.2.1.1, p. 4-50, third paragraph Palmer and Bernhardt show impairment to "correlate" with these ions but do not produce actual "causal" factors of potential impairments. This discussion does not state what type of impairments, if any, are being made because of specific ions.	OSMRE has reviewed the text in question and made revisions in accordance with the comment.
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.10.2.6, p. 3-331 "Several state parks lie within this region including…." OSMRE should modify this sentence to state that several	Thank you for the comment. Corrections have been made to this text in the FEIS.

BENEFITS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		state parks and state Wildlife Management Areas lie within this region. Additionally, Big South Fork National River and Recreation Area should be included in the list of sites.	
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.11.3, p. 3-353"3.11.3 Visual Resources by Region"Visual resources are presented in section 3.11.2. It appears that this section should read "Noise" or "Noise Resources."	The section title has been edited.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.1.1, p. 4-48, second paragraph "The regulatory authority uses this assessment of the probable hydrologic consequences and other available information to prepare the cumulative hydrologic impact assessment and to determine if the permittee has designed the proposed operation appropriately to prevent material damage to the hydrologic balance (30 CFR 780.21 and 784.14). The regulatory authority cannot approve the permit application unless the applicant successfully shows that the proposed operation has been designed to prevent material damage to the hydrologic balance outside the permit area (30 U.S.C. § 1260(b)(3); 30 CFR 773.15(e))." The concept of cumulative hydrologic impact assessment (CHIA) analysis is not new. The Proposed SPR, however, makes it clear that permit applications will not be processed until the CHIA analysis is complete for that area or district. The DEIS does not discuss how this would work, including the potential need for more review staff within the regulatory agencies.	As provided in § 780.19(f) of the final rule, the regulatory authority may not approve a permit application until the hydrologic, geologic, and biological information needed to prepare the CHIA has been made available to the regulatory authority and the regulatory authority has used that information to prepare the CHIA. This is not a new requirement. Per existing regulations at 30 CFR 773.15(2)(e) the regulatory authority cannot approve the permit application until the regulatory authority has "made an assessment of the probably cumulative impacts of all anticipated coal mining on the hydrologic balance in the cumulative impact area and has determined that the proposed operation has been designed to prevent material damage to the hydrologic balance outside the permit area". Therefore there is no need for the DEIS to discuss how this existing requirement would work, and no need for additional review staff.
OSM-2010-0021-0696	Murray Energy Corporation	Action Alternatives and Potential Effects on Water Resources Section 4.2.1.2, p. 4-55 to 4-57, Table 4.2.1-1 "Primary Effects on Water Resources in Comparison to the No Action Alternative " column. In this column, most of the Proposed SPR elements would not directly result in "improved stream water and groundwater quality" and "preserve streamflow and groundwater quantity," as the table implies. While some of these elements could directly affect water resources under certain circumstances, the question of whether some of the Proposed SPR elements affect water resources in comparison to the No Action	OSMRE agrees that analysis of the effects on water resources at the mine level is important to understand. However, due to the broad geographic scope of the SPR, OSMRE is unable to forecast potential effects at site-specific resolution given the wide range of natural variability. The 13 model mines across the seven major coal regions were developed in order to capture regional variability in terms of mining methods as well as regional context as much as was feasible.

BENEFITS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		Alternative depends on site-specific conditions and does not support the need for an action alternative as OSMRE represents.	
OSM-2010-0021-0696	Murray Energy Corporation	Analytic Methods for Surface Water ResourcesSection 4.2.1.3, p. 68, first paragraphOSMRE's third step multiplies the average number of stream crossings on mine permit land by the average spatial extent of downstream water quality effects (6.2 miles) to estimate the total number of downstream miles affected by coal mining. By doing so, OSMRE is building uncertainty upon uncertainty in its analysis and exponentially overstating the impact of mining activity on downstream surface water quality. Consequently, OSMRE's approach is scientifically and statistically less and less defensible with each subsequent step in the analysis.	OSMRE acknowledges the effect that multiplication and multiple steps have on uncertainty. However, the analysis has minimized the number of steps specifically to mitigate compounding uncertainty. In addition, a comprehensive sensitivity analysis was performed to assess the variables that contribute most to model output. This analysis is discussed in detail in the RIA.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.1.3, p. 4-69, second paragraph "While data are not available to determine whether the Action Alternatives would reduce the number of downstream miles adversely affected by mining, implementing the Action Alternatives (excluding Alternative 9) would at least reduce the level of adverse effect within the 6.2-mile downstream areas." OSMRE's admission that data are not available calls into question the validity of using a model that does not have factual support. Concluding that, even though there are no data to back a model assumption, the assumption should be made anyway does not represent best available science and is illogical. Using 6.2 miles is particularly inappropriate for western ephemeral and intermittent streams that may not connect to any downstream surface flows.	Please refer to Master Response on Water Quality Benefits.

BENEFITS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.1.3, p. 4-63 "To quantify the broader, national Benefits of the Action Alternatives, the analysis translates the reduction in streams filled and the increase in stream miles restored into an average change in impacts per ton of coal produced for the modeled "typical" mines in each region. Then the analysis applies this multiplier to the estimated production (tons of coal produced) in each region under each Alternative." OSMRE fails to define a "typical mine" and how the characteristics of OSMRE's typical mine differ from the characteristics of each type of mining operation in different mining regions throughout the U.S. As written, it is difficult to understand if OSMRE has appropriately captured characteristics that reflect current and likely future mining practices.	Thank you for your comment. Section 4.2.1 describes the methodology for quantifying changes to stream impacts anticipated to result from rule implementation. The volume of coal for each modeled mine type was estimated using 2015 MSHA data on coal production by mine. The calculation is based on the total amount of coal produced by each model mine type for each region to address this comment The text in Section 4.2.1.3 has been clarified.

7. Environmental Impacts of Coal Mining

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
OSM-2010-0021-0066	NMA	The definition of buffers is also problematic. The alternatives in the DEIS apply consistently wide buffers along all streams (with some categorical exclusions for smaller streams) which fails to account for the differences in ecological function of streams. The alternatives should have included variable buffer widths reflecting the differences in ecological function. The DEIS does not provide support for the selection of 100-foot buffers, to be implemented across all stream types. The 100-foot buffer appears to be arbitrary and unsupported by any technical or scientific information. Alternative buffer widths should have been evaluated in context with their function on various stream types.	Thank you for your comment. Please refer to Master Response on Alternatives. Please also see the discussion of buffer widths, and planting requirements for the buffer, as contained in the preamble for the final rule. We have made changes to the final rule in response to public comment on these issues.
OSM-2010-0021-0066	NMA	Additionally, per OSMRE's DEIS, all ephemeral streams would be included in the definition of intermittent or seasonal; hence, the definition fails to differentiate the stream types. The document cited in the DEIS in support of this definition is a 1923 document. We suggest that OSMRE rely on relevant and contemporary information to support any proposed definition.	Please see the preamble for section 701.5 of the final rule for discussion of the science behind the regulatory definitions of streams as ephemeral, intermittent or perennial. The 1923 reference is to a document that provides a concise and useful description of basic stream classification concepts that similar to other basic information on scientific principles is not subject to becoming out of date.
OSM-2010-0021-0066	NMA	The Preferred Alternative, the no action alternative, and many of the other alternatives place a 100-foot buffer on each side of all perennial and intermittent streams regardless of their function, and the preferred alternative also requires restoration of a 100-foot buffer for ephemeral streams. In order to diverge from these strict buffer requirements, permit applicant must prove, on a case-by-case basis, that an alternative buffer or approach would not result in material harm to the hydrologic balance, as that term has been unreasonably defined by OSMRE. This one-size-fits-all approach to stream buffers makes it clear that OSMRE did not enlist scientific experts on stream function nor provide sufficient consideration of possible approaches to minimize and avoid impacts to streams.	Please see the discussion of buffer requirements in the rule preamble at 780.28 and 816.57.
OSM-2010-0021-0066	NMA	(proceeded by synthesis of ephemeral stream ecological literature) The Preferred Alternative, the no action alternative, and	Please see the rule preamble for discussions of the basis for the requirements by stream type.

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		many of the other alternatives place a 100-foot buffer on each side of all perennial and intermittent streams regardless of their function, and the Preferred Alternative also requires restoration of a 100-foot buffer for ephemeral streams. This one-size-fits-all approach to stream buffers makes it clear that OSMRE did not enlist scientific experts on stream function nor provide sufficient consideration of possible approaches to minimize and avoid impacts to streams. In summary, applying the buffer requirements and specific monitoring requirements (without consideration of the stream characteristics) cannot be supported by the scientific literature.	
OSM-2010-0021-0066	NMA	The analytical suite required to be sampled in intermittent and perennial streams for surface water and groundwater under most of the alternatives, including the Preferred Alternative, includes temperature, total suspended solids (only surface water), aluminum, bicarbonate, sulfate, chloride, calcium, magnesium, sodium, potassium, (hot) acidity, alkalinity, pH, selenium, specific conductance, TDS, total iron, arsenic, zinc, copper, cadmium, ammonia, nitrogen, and total manganese. It is not clear how this set of constituents was selected or why they would be pertinent to all mining areas in the U.S. There are two paragraphs in the DEIS that address the inclusion of these constituents [....] All of the cited studies were conducted in Appalachia. There is no evidence of impaired water quality provided for any of the other mining regions of the US. Three of the cited studies do not even address water quality, one of the studies documents water quality downstream of a mine that was abandoned long before the existing rules came into effect, and some of the studies merely document water quality but do not provide a comparison to control streams. In total, the cited studies do not adequately support the statement of need to monitor this suite of water quality parameters nationwide.	In the final version of the Preferred Alternative we have deleted the six parameters (ammonia, arsenic, cadmium, copper, nitrogen, zinc) that we had added the Preferred Alternative at U.S. EPA's request. Our research found that those parameters have little or no nexus to coal mining. Instead, they appear to relate to placement of coal combustion residues in mines, which is the subject of a separate rulemaking.
OSM-2010-0021-0066	NMA	The need for monitoring and the constituents that need to be addressed will vary considerably with the location of the mine relative to streams, the geology in the area of the mine, and the mining approach. All actions in and around streams must be permitted under the CWA. CWA permit requirements typically identify constituents and monitoring required based on local conditions and the specific mining	The Clean Water Act is not as comprehensive as SMCRA with respect to protection of the hydrologic balance. The Clean Water Act does not require establishment of a premining baseline and it only requires monitoring of point-source discharges. SMCRA requires that permit applications include baseline

ENVIRONMENTAL IMPACTS OF COAL MINING

COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		approach, with mitigation, that is proposed. As such, any requirement for additional water quality monitoring in the SPR is redundant with other federal regulations and is totally unnecessary.	information so that the potential impacts of mining can be assessed at the time of permit application and so that impacts that occur during mining and reclamation can be readily identified and evaluated. SMCRA also requires monitoring of both the quality and quantity of surface water and groundwater, as well as monitoring sites located above and below the mine site. Therefore, deferral to state Clean Water Act authorities would not achieve the same results as the stream protection rule.
OSM-2010-0021-0068	Earthjustice	OSMRE recognizes that elevated concentrations of alkaline ions in mine drainage cause increased stream conductivity, which is highly correlated with biological impairment downstream from mine sites [...] OSMRE proposes to remedy this problem in three ways: (1) by "requiring that backfilling techniques consider impacts on electrical conductivity," (2) by "requiring that excess spoil fills be constructed in compacted lifts," and (3) by "incorporating elements of the Forestry Reclamation Approach into our soil reconstruction and revegetation rules." Id. OSMRE cites no scientific evidence that any of these three methods is likely to be successful.	No changes are necessary in response to this comment. OSMRE does not maintain that these measures are a complete solution in addressing increased stream conductivity. As discussed in the preamble to the final rule, specifically in the discussion of Section 780.12, the intent is to minimize compaction of soil materials in the root zone, while still requiring compaction of spoil in order to minimize conductivity levels in leachate and mine runoff. Performance standards with Section 816.38(a) requires compaction to prevent acid-forming materials from leaching into the soil because our experience has shown that surrounding the material with compacted low permeability material is necessary because spoil is known to be highly variable in terms of hydraulic conductivity.
OSM-2010-0021-0061	Peabody Energy	The current indicator parameters are quite sufficient. There has been no showing in the DEIS that current practices are not doing the job. Examples of water quality problems are a few studies in Appalachia, mostly in areas with prelaw discharges. Regional issues should be addressed on a regional basis.	OSMRE agrees that parameters of concern (or indicator parameters) as used in the comment, should take regional characteristics, in fact site-specific characteristics, into consideration. As such these parameters are to be determined by the regulatory authority. The regulatory authority is in the best position to identify those local parameters of concern, if applicable, and include them in the required baseline monitoring data. Any parameters of concern the regulatory authority identifies will more accurately reflect the constituents that could potentially impact water resources during

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
			coal mining and reclamation activities in their specific region of the country. We anticipate that, during the development of the permit application package, the applicant will take part in this process by consulting with the regulatory authority about which, if any, additional parameters should be added to the baseline monitoring plans.
OSM-2010-0021-0049	Interstate Mining Compact Commission	In addition, the proposed requirements are not based on data collected from state wildlife agencies or from private landowners and citizens regarding reclamation alternatives for wildlife habitat. OSMRE should consider 1) the long term wildlife conservation and habitat objectives for coal basin regions, 2) the habitat management decisions they will allow a private landowner to make, 3) how private landowners must manage for wildlife that depend on 100% forested habitats, and 4) which suite of wildlife species and which ecological niche are the most important conservation objectives for each region, especially on private lands.	No changes are necessary in response to this comment. Fish and wildlife habitat remains as an approved post-mining land use.
OSM-2010-0021-0696	Murray Energy Corporation	Chapter 3 Large sections of Chapter 3 are missing citations; hence, the underlying data/analyses used by OSMRE to support much of the discussion cannot be verified.	Thank you for the comment. After reviewing chapter 3 of the DEIS in regard to your comment we agree that it appears that some sections of the chapter should have included more citations to the applicable source references. This has been corrected in the FEIS.
OSM-2010-0021-0696	Murray Energy Corporation	Total Resources Section 3.1.1.1 OSMRE relies inappropriately on outdated coal reserve information; these data should be updated for each region. OSMRE must compile recent information from specific mining regions and for mining methods. For example, the EI A has more recent data (http://www.eia.gov/coal/annual/), which OSMRE should include for this critical set of statistics.	While OSMRE acknowledges that new EIA data from the 2014 assessment are available, the Total Resources section (3.1.1.1) describes coal reservoirs and production based on the 2012 EIA report. A comparison of the 2014 (2016 report) values with those in the 2012 report indicates that these budget values are generally very similar and updating the section with the more recent values would not alter discussion.
OSM-2010-0021-0696	Murray Energy Corporation	Estimated Recoverable ReservesSection3.1.1.4,14p. 3-9O SMRE's sources of information regarding underground mining practices are not provided, and the information therefore cannot be verified. For example, the statement that underground mining and coal processing losses are typically 17 to 25% higher than that of surface mining is not	The reference (Luppens, 2009) is given at the beginning of the section, see the second paragraph under Section 3.1.3.4 on page 3-7 of the DEIS. The statistic regarding underground mining and coal processing losses in comparison to surface mining losses comes from page 14 of

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		supported.	Luppens (2009).
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.1.4, p. 3-18 Illustrations in this section inaccurately portray surface mining methods. For example, Figure 3.1-9 on page 3-19 shows a dragline in the wrong position; Figure 3.1-10 on page 3-20 shows spoil present downslope from the outcrop, which is illegal. Another example of inaccurate depiction of mining methods appears in discussions of area mining and mountaintop mining. The authors neglect to mention that modified area mining was developed for coal reserves that had outcrops in lands with limited to moderate relief. Mountaintop mining is modified area mining in steeply sloping lands. OSMRE should accurately depict and describe surface mining methods. Failure to do so will lead the reader to inaccurate conclusions about how operations are conducted. Drawings created forty years ago by Tony Haley of Caterpillar provide more accurate pictures of haul-back mining on contour benches than those in the DEIS.	Thank you for the comment. We agree that there are errors in the figures described and these have been removed. The narrative section has also been modified to more accurately reflect current practices.
OSM-2010-0021-0696	Murray Energy Corporation	Open Pit Mining Figure 3.1-14, Section 3.1.4.3, p. 3-24 The photograph in Figure 3.1-14 does not depict open-pit mining for thick coal, which it purports to do.	Thank you for the comment. The comment is correct and we have removed the figure.
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.3, p. 3-87 There is a substantial amount of information about soils, including electronic soil surveys, in the Natural Resources Conservation Service (NRCS) web survey pages: http://websoilsurvey.sc.egov.usda.gov/App/HomePage.htm OSMRE should use this valuable source in this section.	The NRCS web survey pages are an excellent resource for obtaining data on specific soil series and their chemical and physical properties, as well as their geographic extent. The DEIS used NRCS soils data to depict the presence and extent of soil orders nationwide (see the figures in section 3.3), and within the text provides other appropriate sources describing regionally typical conditions for important soil characteristics such erodibility and productivity.
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.3.1, p. 3-88"Soil consists of the horizons near the earth's surface that, in contrast to the underlying parent material, have been altered by the interactions of climate, topography, and living organisms over time."Soils are formed by five factors: parent material, climate, topography, vegetation, and time. As a result, the soil horizon will have many of the characteristics of the parent material, especially in shallow and/or poorly developed soils, where the soils are a direct reflection of the	Thank you for the comment. The quoted text does not contradict the information provided in the DEIS nor does it provide critical information lacking from the DEIS discussion. No change is necessary in response to this comment.

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		weathered parent material from which they were derived (Jenny, 1994).	
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.3.1, p. 3-88 "However, the lowest depth of biological activity is difficult to discern." The limits of organic activity within a soil profile are generally observed when there is a lack of brown color. The transition to an area void of organic activity can be quite drastic, especially in younger, less developed soils.	Thank you for the comment. The text referenced in your comment is discussing gradation from soil to hard rock or earthy materials that are devoid of animals, roots, or other marks of biological activity. Color is one indication of the presence of biological activity but is not universally definitive. No change is necessary in response to this comment.
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.3.1, p. 3-89 Soil distribution can be very heterogeneous, creating a mosaic of soil types over small areas. This statement is correct and it is precisely why the characterization of soils by regions in sections 3.3.2 through 3.3.8 can be very misleading.	The broad generalizations in the soils discussion are necessary due to the nationwide scale of the proposed rulemaking effort. Site specific soils information would be appropriate for a document reviewing a specific permit area, but this level of detail is neither possible nor necessary to inform the decision between alternatives on this nationwide rulemaking.
OSM-2010-0021-0696	Murray Energy Corporation	Surface Water OverviewSection 3.5.2.3, p. 3-131"Surface water can also include a portion of precipitation that has infiltrated into the soil or geologic matrix during or immediately after a precipitation event, and traveled as subsurface flow ultimately discharging into a stream or lake (interflow) or to the ground surface at topographic lows (through flow)."OSMRE is incorrect. USGS (see e.g., http://pubs.usgs.gov/circ/circll86/html/gen_facts.html) and countless academic textbooks (including what is widely considered the definitive classical treatise on the topic of groundwater written by Freeze and Cherry, 1979) would assert that OSMRE is describing groundwater, and not surface water, flowing subsurface after precipitation. This statement does not accurately reflect the conventional behavior of surface water/precipitation that infiltrates soil or geologic matrices following precipitation events. The water that OSMRE describes as infiltrating the ground after precipitation and traveling subsurface to a stream or lake is groundwater.	Edits made to clarify the text discussion of groundwater discharge into surface water as a source of surface water flow. See section 3.5
OSM-2010-0021-0696	Murray Energy Corporation	Surface Water Overview Section 3.5.2.3, p. 3-134 "Using this method, streams are numbered progressively from the headwaters or drainage basin divide to a downstream location. Headwater streams with no	We have made edits to the discussion of stream ordering (see section 3.5.2.3) for clarity. However the descriptions of headwater streams vary throughout the document as necessary depending on the specific context of the

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		tributaries are designated as first order." The definition of headwater streams in the DEIS is unclear and varies throughout the document. In particular, it is impossible to tell whether streams with no tributaries are the only type of stream classified as headwater streams, or whether headwater streams also include streams of higher-order. In the cited statement, OSMRE should make the following modification: "Using this method, streams are numbered progressively from the drainage basin divide to a downstream location." The second sentence should be removed.	discussion.
OSM-2010-0021-0696	Murray Energy Corporation	Surface Water OverviewSection 3.5.2.3, p. 3-134OSMRE does not justify why it relies on the Rosgen stream channel classification system, which was developed in the 1990s. Other more recent classification systems exist that rely on current science and technology to better characterize and describe ecological attributes and capture land use change...The entire DEIS is directed at the protection of streams; thus the use of a reliable stream classification system is essential. OSMRE should use a more recent and accurate stream classification system. At the very least, OSMRE should explain its reasoning for using this outdated classification system. (Literature about classification system is present below this comment)	The Rosgen system is an accepted classification system and is widely and currently used. The comment is incorrect in the assertion that this system is outdated.
OSM-2010-0021-0696	Murray Energy Corporation	Surface Water Overview Section 3.5.2.3, p. 3-141 "For example, streams whose watersheds are located in high precipitation areas are expected to have the most consistent flows and most frequent floods." OSMRE should support this statement with more quantitative information. Flood frequency can be easily attained from the USGS for all mining regions in the U.S.	Edits were made to the text in response to this comment. The text has been revised to state that flooding occurs more frequently in these areas, instead of the definitive "most" used in the original version of the text. See section 3.5.2.3.
OSM-2010-0021-0696	Murray Energy Corporation	Gulf Coast Coal-Producing Region Section 3.5.3.3, p. 3-164 "As a result of heavy usage for irrigation and municipal purposes, many areas of Texas are experiencing significant declines in water levels in the Carrizo-Wilcox aquifer. Over the past 70 years, levels have dropped by as much as 500 feet in some areas. Dewatering to facilitate lignite mining has also resulted in lower water levels in the vicinity of some active operations (Ashworth and Hopkins, 1995)."	Edits have been made to section 3.5.3.3. The sentence regarding dewatering from lignite mining is not directly supported by the reference, and so we have removed it.

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		According to the DEIS (at 3-172), agricultural usage of groundwater accounted for over 82% of groundwater usage in this area. Mining accounted for approximately 0.3%. OSMRE appears to be attributing a portion of the depletion of the Carrizo-Wilcox aquifer to coal mining in Texas. OSMRE should clarify the degree of dewatering directly attributable to mining operations.	
OSM-2010-0021-0696	Murray Energy Corporation	Air Quality, Greenhouse Gas Emissions, and Climate ChangeSection 3.6, pp. 3-202 to 3-210Section 3.6 makes multiple references to the Four Corners Power Plant and Navajo Mine Energy Project (FCPP) EIS. For example on Page 3-202, the FCPP EIS is cited in lieu of a detailed discussion of coal mining and power generation emissions sources...OSMRE should make this document available to reviewers and allow time for review of and comment on this important reference document.	The FCPP EIS is available at http://www.wrcc.osmre.gov/initiatives/fourCorners.shtm. Additional time for review of the document is unnecessary. The document was and has been available since the publications of the Draft Stream Protection Rule EIS, in addition to having gone through extensive public review and comment during its own development.
OSM-2010-0021-0055	Rocky Mountain Elk Foundation	One of our main concerns is that for new mining operations on currently forested lands, the baseline should not be current condition but rather historic condition	The appropriate baseline for the analysis is the current operation without the Proposed Action. Please refer to OMB's Circular A-4 for details about how to conduct a regulatory impact analysis.
OSM-2010-0021-0696	Murray Energy Corporation	OSMRE's alternatives in the DEIS fail to address current practices and considerations involving revegetation. OSMRE claims that failed reforestation efforts have resulted in compacted grasslands that do not represent native pre-mining vegetation. However, OSMRE continues to ignore current and evolving reclamation practices and planning efforts, such as those described by Wang et al. (2013).	We describe current practices and documented impacts involving revegetation under the No Action Alternative in Chapter 4.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.2.2, p. 4-101, first bullet Under Alternatives 2, 6, and 8 (Preferred) all stream reaches within or adjacent to coal mining operations require a 100-foot riparian buffer (whereas the No Action Alternative provides qualitative guidance on activities bordering waterways). By implementing specific criteria to be met during and after coal mining operations, the likelihood of disrupting habitats and associated wildlife is decreased. This buffer Benefits not only the flora and fauna occupying the riparian habitat, but also the connected terrestrial and aquatic communities beyond the permitted site. OSMRE does not describe the same requirements found in the previous impact descriptions or alternative analysis and should clarify whether a 100-foot buffer is required.	The text cited by the commenter states that a 100-foot riparian buffer is required under these Alternatives. This is correct.

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
OSM-2010-0021-0066	NMA	The technical experts reviewed Chapter 4 in search of support for the statements in Section 1.1 that are intended to justify the need for changes in the regulations. Not infrequently, the citations provided fail to support the statement in the DEIS. For instance, on page 4-50 of the DEIS, OSMRE states: Under existing regulations, mining continues to affect downstream water chemistry. Studies have shown that mining-impacted waterways often contain elevated levels of iron, aluminum, manganese, and sulfate. These waters typically have lower alkalinity concentrations and lower pH, while specific conductivity and total suspended solids are typically higher, as compared to streams unimpacted by mining (Wangsness et al., 1981; Zuehls et al., 1984; Cravotta, 2008; Paybins, 2003; Howard et al., 2001; Stauffer and Ferreri, 2002; Bryant et al., 2002; Hartman et al., 2005; Pond et al., 2008; Petty et al., 2010). All of the cited studies were conducted in Appalachia with a focus on surface mining impacts. There is no evidence of impaired water quality provided for any of the other mining regions of the US. Three of the cited studies do not even address water quality; one of the studies documents water quality downstream of a mine that was abandoned long before the existing rules came into effect; and some of the studies merely document water quality but do not provide a comparison to control streams. Even collectively, the cited studies do not adequately support the statement or the need for a new rule to be applied nationwide.	The literature cited in Section 4.2.1 as evidence of mining impacts on water quality has been reviewed and refined in the FEIS. Several citations (U.S. EPA, 2011, Presser, 2013, and Herlihy et al., 1990) have been included to add support that mining leads to elevated downstream concentrations of contaminants.
OSM-2010-0021-0066	NMA	"Acid mine drainage has historically been a primary concern associated with coal mining due to the effects of low pH on the viability of the system for aquatic life, and impacts on human use and enjoyment of the water. Generally, aquatic life forms do best in a pH range of 6.5 to 9.0. Outside this range, certain analytes become more toxic to aquatic life (Lowry et al., 1983). This concern is relevant to mining nationwide, although not as prevalent in the western coalfields, where the geology, soils and hydrology provide high buffering capacity (alkalinity). For example, in coal regions of the Colorado Plateau and Northern Rocky Mountains and Great Plains, if sulfuric acid forms through the oxidation of sulfide materials within mine spoil and waste, it is usually neutralized by the highly alkaline conditions of surface waters in this region (Lowry et al.,	The paragraph cited by the commenter has been revised. Specifically, references to published scientific literature have been added in support of the first and fourth sentences of the cited paragraph. Sentences which could not be supported have been removed. We have also stated that while coal mining contamination is likely occurring in western United States streams, impacts from acid and alkaline mine drainage are more difficult to observe given the arid climate of coal fields in this region.

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		1983)."No evidence was provided to support the 1st, 2nd, or 4th sentences in this paragraph. The 3rd sentence is correctly supported. The last sentence is partially supported. Lowry et al. (1983) did an investigation in the Powder River area of Wyoming, not the broader area suggested by the sentence. Lowry et al. also speculated that the high alkalinity of the area was neutralizing sulfides, so the sentence is partially supported. The primary subject of the paragraph is acid mine drainage effects on aquatic life and human uses. What the paragraph fails to point out is that Lowry et al. (1983)—the only cited source in the paragraph—concluded that acid drainage was not an issue in the Powder River area. Therefore, the primary thesis of the paragraph is not supported by any cited literature or scientifically collected evidence.	
OSM-2010-0021-0066	NMA	The two paragraphs following the paragraphs discussed above rely solely on Palmer and Bernhardt (2009). That document is a working document and not a peer-reviewed scientific study. If the issues discussed in those paragraphs were well documented, better support of the statements would be expected. Many of the statements in Chapter 4 rely upon documents that pre-date the existing rule, so those documents are no longer applicable to a discussion of the need for a revised rule. For example page 4-52 states:*Higher infiltration rates on mined areas increased stream base flow, and increased storage capacity in replaced mine spoils reduced peak flow in streams receiving drainage from mine sites (Corbett and Agnew, 1968).*A 1968 document cannot be assumed to be reflective of current conditions under the existing rule. Therefore, this statement is not supported by any evidence of a continuing effect.	Chapter 4 includes extensive discussion of the current conditions of the resources that may be affected by the SPR, and some discussion provides support for why revised regulation of mining as it relates to these resources may be needed. As a result, it is appropriate for data sources that pre-date the proposed rule be cited in the EIS.
OSM-2010-0021-0066	NMA	This lack of support for statements that appear to be scientific in nature continues throughout the DEIS, and the overwhelming majority of the cited documents address studies conducted in Appalachia; very little information in other mining areas is provided.	Please refer to Master Response on Regional Nature of Impacts.
OSM-2010-0021-0066	NMA	The inclusion of underground mining in the SPR is particularly confusing. Section 4.2.1.3, page 4-68 (third bullet) of the DEIS states: "The engineering analysis found that direct stream impacts from underground mines were temporary; therefore, downstream improved miles from	OSMRE agrees that surface and underground mining methods are very different in technology, geography, potential environmental impacts. For this reason, OSMRE identifies separate regulations for surface and

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		underground mines are not quantified." This statement alone suggests that implementation of new regulations on underground mining to protect streams and aquatic resources is unnecessary, and, at the least, are not supported by sound data. If the Proposed Action is to revise regulations to surface mining, the action cannot be applied to underground mining. It is obvious that the two mining methods are very different in technology, geography, potential impact and mitigation strategies.	underground mines and the RIA and EIS analyses define 13 model mines of which five are underground.
OSM-2010-0021-0066	NMA	Bernhardt and Palmer (2011), Palmer et al. (2010), Pumure et al. (2010) and Lindberg et al. (2011) address effects of mountain top valley fills in Appalachia. In the description of the existing rule in the DEIS (page 2-8) the DEIS states "the agencies administering the Clean Water Act have implemented policies that have sharply reduced both the number of excess spoil fills and the length of stream covered by those fills. Furthermore, the regulations in 40 CFR Part 230 for implementation of section 404(b)(1) of the Clean Water Act require an analysis of all practicable alternatives to placement of fill material in waters of the United States, which would include most streams. Under those regulations, the applicant must select the alternative with the least adverse effect on the aquatic ecosystem and mitigate any remaining adverse impacts on the aquatic environment." Therefore, the studies conducted by Bernhardt and Palmer (2011), Palmer et al. (2010), Pumure et al. (2010) and Lindberg et al. (2011) addressed the effects of legacy mining and are not pertinent to the evaluation of the adequacy of the existing rule. Pond et al. (2008) documented a study that was also conducted in Appalachia evaluating the effects of valley fills on macroinvertebrates. Not only is that document not pertinent since it evaluated the effects of legacy mining, it does not address water quality. Agouridis, et al. (2012) evaluated water quality run-off in areas that had been filled to support restoration efforts. They monitored a number of parameters and found that most did not persist although conductivity approached reported levels of concern. The document does not support the statement in which it is cited.	The EIS text relevant to the citations discussed by the commenter states that "Excess spoil fills constructed during large-scale mining operations in steep-slope areas may impact aquatic ecosystems by, among other things, increasing ion concentrations in receiving waters. These impacts may occur both during the mining activity and after reclamation." OSMRE disagrees with the implication in the comment that the cited studies, which examine impacts of mining that occurred prior to the implementation of current policy effected under the 2009 MOU among the U.S. Department of the Interior, U.S. Department of the Army, and U.S. EPA on implementing the Interagency Action Plan on Appalachian surface coal mining, are not pertinent to the evaluation of impacts under existing regulations and policy. The regulations cited in the comment have not eliminated impacts; selection of the alternative with the least adverse effect as required under the CWA does not equate to avoidance of all effects. OSMRE acknowledges that the policies referred to here, specifically including those arising from the 2009 MOU, have resulted in substantial changes in how mining operations are reviewed and permitted. The studies cited in this part of the EIS discussion are valuable to determine what requirements need to be included in regulation to ensure the continued implementation of these policies.

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
			Pond et al. (2008) investigates the effects of degraded water quality, specifically elevated specific conductance, in mined streams using changes in the biological community as a metric to evaluate the consequences. The results presented in Pond (2008) were a key consideration that led to the development of the 2009 MOU. The other studies cited are also valuable to the consideration of impacts that persist under existing regulations. Palmer et al. (2011) presents data that indicates mine-related water contaminants persist below valley fills despite existing requirements. Similarly Lindberg et al. (2011) identifies high conductivity and increased sulfate concentrations in tributaries draining currently active mountaintop mining catchments in West Virginia. The Lindberg study was focused on cumulative impacts and therefore looked at chemical signatures of mountaintop mining impaired streams impacted by both current and historical activity. Palmer et al. (2010) specifically poses a concern that current attempts to regulate mountaintop mining and valley fill practices are inadequate and that current mitigation strategies are not adequately compensating for lost stream habitat and function. Bernhardt and Palmer (2011) describe the adverse effects caused by mining related elimination or fragmentation of native habitat, an impact which is not specifically addressed under current regulation or policy and which indirectly relates to water quality. We have however, removed the reference to Agouridis et al. (2012) from the text. While Agourdis et al. did examine relevant mine-related impacts, specifically it examined the runoff from mine spoils, the focus of the study was actually on the impacts of forestry reclamation and therefore this study is not particularly germane to the discussion of water quality impacts from excess spoil fills.

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
OSM-2010-0021-0066	NMA	None of the cited literature supports a conclusion that additional water quality sampling is required, or that chemical constituents will persist over time under the existing federal regulations (including the CWA). All but one of the cited studies was conducted in Appalachia, and all but two of the studies were focused on valley fills. None of the cited studies address underground mining. Thus, the DEIS does not include any evidence that additional water quality monitoring is needed	OSMRE acknowledges that much of the research on understanding downstream effects of coal mining has been conducted in Appalachia. The history and extent of mining in the Appalachian Basin makes it the subject in the majority of the water quality studies (e.g., Lindberg et al., 2011, Merriam et al., 2011, Petty et al., 2010, Pond et al., 2008, Fulk et al., 2003). In addition, authors have also noted that due to the arid climate and high mineralization of stream water, analyses of this type are more difficult in western regions. Though limited, literature in other regions indicates similar downstream impacts despite obvious difference in geography. To account for these differences, model mines were developed to represent geography, coal production, and other environmental factors of each coal mining region.
OSM-2010-0021-0696	Murray Energy Corporation	Second, pages 4-52-4-53 of the DEIS have a section on the "Physical Effects on Groundwater." Citing a 1997 study, this discussion describes how subsidence can affect groundwater flows. But this section also does not examine whether these potential effects are addressed by current regulations. Moreover, OSMRE has engaged in rulemaking to protect streams for decades without deciding until it proposed the SPR this year that it was necessary to change how it regulates subsidence impacts on streams. Obviously, a 1997 study cannot be the basis for deciding that it is now necessary to change the agency's regulatory course.	The EIS text references the Trapp and Horn study to explain the mechanisms through which subsidence affects the movement of groundwater. This discussion therefore is not subject to becoming dated due to changing regulations. The Trapp and Horn study is not used to support the need for the change to regulations in any context of the EIS, the rule or the rule preamble.
OSM-2010-0021-0696	Murray Energy Corporation	Third, pages 4-53 -4-54 of the DEIS contain a discussion of "Subsidence and Effects on Surface Water and Groundwater" that at least tries to show that the current regulatory regime is failing to address subsidence impacts on streams. OSMRE claims that "[s]everal studies have documented subsidence-related impacts to hydrologic systems that continue under our existing regulations." DEIS at 4-53. But the studies do not provide the necessary support for OSMRE's changed regulatory approach. Two of the studies, Carver and Rauch (1994) and Slaughter et al. (1995), are old. As just discussed, OSMRE has conducted decades of ongoing rulemaking concerning mining impacts on streams	While not the driving factor behind the proposed Stream Protection Rule, the 1994 study by Carver and Rauch and 1995 study by Slaughter et al. do provide supporting evidence related to impacts would be addressed under the proposed rule.

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		without concluding that it was necessary to adopt new regulations as to subsidence impacts. Presumably, OSMRE has some new information that now leads it to a different conclusion. Studies that are more than 20 years old, however, can hardly be characterized as new information.	
OSM-2010-0021-0049	Interstate Mining Compact Commission	Alternative 1 (No Action Alternative) 4.2.1.5, p. 4-77 "Under the No Action Alternative, no changes in mining practices would occur and current water quality issues would likely persist. Subsection 4.2.1.1 above describes these issues in detail. They include pH impacts from acid mine drainage, elevated concentrations of iron, aluminum, manganese, and sulfate; sedimentation in the water column; flow alteration and stream elimination as a result of mining through streams and spoil management practices; drawdown of groundwater levels,· and degradation of groundwater through increased concentrations of sulfate, iron, and other pollutants." OSMRE states water quality issues would persist as if each coal mine is the same in regards to water quality and geology when in fact they are not and vary significantly region to region. NPDES regulations already exist and are being used daily to address potential issues.	The description of the No Action Alternative has been updated to reflect that each mining system is unique and that no other actions in addition to those already in place would be implemented.
OSM-2010-0021-0049	Interstate Mining Compact Commission	Alternative 1 (No Action Alternative) 4.2.2.1, p. 4-94 through 4-96"Adverse impacts would continue to occur ..."The summary statement for this section mentions only adverse impacts and does not identify any beneficial impacts. The impacts of mining and then reclamation, particularly in a region and landscape dominated by forest cover (Central Appalachia), are beneficial to many species, including several species of concern and wildlife species that are popular and important for wildlife viewing and hunting. In the CAPP region, the game species that benefit from mining include white-tailed deer, elk, turkeys, rabbits and Bobwhite quail. The other species include grassland and shrub/scrub songbirds, Northern harriers, Short-eared owls, and several small mammals.	No change is needed to the text. The section acknowledges that the No Action Alternative has many mechanisms in place for ensuring protection of fish, wildlife, and related environmental stressors.
NA	EPA	We recommend that the FEIS more thoroughly present the state of the science as to the physical, chemical and biological effects of surface and underground mining operations on the aquatic environment. The DEIS does not discuss the existing scientific literature (and multiple state	The discussion in the 'Chemical Effects on Surface Waters' and 'Documented Impacts Related to Activities in or Near Streams' subsections of Chapter 4.2.1.1 have been updated to include more discussion of selenium

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		agency datasets) demonstrating that surface mining permits with mining within I 00 feet of a stream result in a high percentage of streams with impairments to aquatic life. We recommend that the FEIS include this relevant information and additional discussion connecting the impacts associated with higher concentrations of TDS/conductivity in reaches downstream of mining activities and the potential to cause material damage to the hydrologic balance.	as an important biologic stressor. Further, the discussion now includes information on the recently developed conductivity thresholds presented in U.S. EPA, 2011.
NA	EPA	We recommend including discussion in the FEIS of important studies published by Presser, 2013 and Presser and Luoma, 20 I 0 which address critical information relating to selenium and its impacts on fish, wildlife as well as impacts at the ecosystem scale.	The recommended studies have been cited in 'Documented Impacts Related to Activities in or Near Streams' of section 4.2.1.1 and other sections to place more emphasis on work done to describe the toxic effects of selenium.
NA	EPA	The document presents a statewide summary of surface water quality conditions based on recent Clean Water Act (CWA) 305(b) and 303(d) reporting data. However, the discussion is general and does not specifically analyze mining-related impairments, even though the DEIS acknowledges that state CWA section 303(d) reports routinely identify coal mining as a pollution source. This additional refinement and analysis would be particularly helpful given that the proposed rule is intended to better protect streams from mining-related impacts. In the absence of this analysis, at a minimum, we recommend that the data be broken out to indicate water quality reporting results for surface waters within the mining regions of each state, rather than the state as a whole. This would allow for a finer depiction of existing water quality conditions in areas where coal mining has historically occurred.	Specific referfences to state-level 303(d) impairments in the Appalachian Region are provided in Chapter 3.6.5. Section 4.2.1 describes Clean Water Act reporting data, which is also discussed in the Cumulative Impacts section (4.5). Also, please refer to Master Response on Water Quality Benefits.
NA	EPA	The discussion in the Environmental Consequences of Alternatives (Chapter 4) focuses almost exclusively on the Appalachian region. Chapter 4 briefly characterizes the extent of physical loss of streams from mining activities from the Appalachian region and relies on a very small data set. We recommend that SMCRA permit data or other similar information be considered to provide a more complete baseline depiction of the physical effects of coal mining activities across all seven coal resource regions of the country. The analysis presented in the DEIS relies upon the assessment of relatively few state waters (e.g., 16 of 26 states whose data is presented in the document have assessed less than 25% of waters). Furthermore, at the scale	As stated in the EIS Chapter 4, absent nationwide data regarding the historical effects of coal mining on streams filled, mined through, or degraded, the EIS describes a number of region- or site-specific studies that evaluate these types of coal mining impacts on streams. This information provides context for understanding the baseline levels of impacts to streams from coal mining. In addition, in response to public comment, the FEIS includes summaries of USACE permit data regarding permitted wetland and stream impacts from coal mining, as well as OSMRE data describing

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		the data is presented, it is not clear whether the assessed waters are representative of conditions within the coal mining regions of each state. U.S. EPA would like to work with OSMRE to consider other ways to present an analysis that gives a more complete depiction of the quality of surface waters and the effects of mining activities on these resources in coal mining regions across the country.	numbers of new mine permits and associated acreage of the new mine permits from 2005 and 2015.
NA	EPA	We recommend that OSMRE include a study by Palmer and Hondula 2014. This study examined 434 stream mitigation projects from 117 surface mining permits and found that most of them still show signs of water quality, habitat, and biological impairments >5 years post-restoration. Further, a joint study by U.S. EPA and OSMRE scientists (Pond et al 2014) regarding the long-term impacts of surface mining on Appalachian stream ecology found that, despite good habitat, the chemical signature was strong enough to impair the majority of the streams studied 15 to 30 years post-reclamation. In preparing the FEIS, we recommend that OSMRE consider whether "restoration" of stream habitats (the most common mitigation requirement under the proposed SPR) will restore biological health downstream of surface mining and valley filling. Studies, including Northington et al. 2011, Palmer 2005, Fritz et al. 2010, have implicated that structural measures such as habitat and invertebrate assemblage quality do not adequately relate to stream functions.	A citation to Palmer and Hondula (2014) has been included in section 4.2.1.1 in the FEIS. The FEIS acknowledges that current mitigation practices fall short of CWA objectives and that it can be difficult to restore biological characteristics given persisting chemical impairment in engineered stream channels based on the analysis of Palmer and Hondula. Additionally the FEIS discusses the fact that current restoration approaches focus primarily on creation of a stable channel instead of the restoration of stream form and function. The EIS recognizes that stream restoration and creation is an emerging area of scientific study and that assessment methodologies for return of biological function in streams are in their infancy in some areas affected by mining. It may be impossible in some cases to precisely mirror the ecological function that was there before mining but the alternatives considered would not require the restoration of identical conditions. However, one of the purposes of SMCRA is to ensure that “surface mining operations are not conducted where reclamation as required the th[e] Act is not feasible”. The Act therefore requires a permit applicant to demonstrate that “reclamation as required [by SMCRA] and the State or Federal program can be accomplished under the reclamation plan contained in the permit application[.]” If reclamation of a stream cannot be accomplished as proposed, then the permit applicant will need to adjust the mining or reclamation plan for the regulatory authority to be able to issue the SMCRA permit.

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
NA	EPA	Page 4-50, line l: Clarify that "water-treatment structure" often involves a sedimentation pond that allows precipitation of particulates, but does not adequately treat dissolved solids. Total dissolved solids (TDS) are discharged from the ponds and a substantial body of scientific literature has now shown impacts of elevated TDS on stream biota (see additional research not cited in the DEIS below).	The definition of water treatment structures in section 4.2.1.1 has been expanded to refer to sedimentation ponds. In addition, a statement following this sentence has been included to indicate that discharge from sedimentation ponds can demonstrate elevated levels of TDS.
NA	EPA	Page 4-66, paragraph 2: We suggest the following information be considered: "In general, these studies describe coal mining's effects on stream quality but do not specify the particular aspect of mine operations that generates the adverse effects." Several researchers have now demonstrated that elevated stream TDS from mining activities negatively affects benthic macroinvertebrate communities (see selected citations below in addition to those in the DEIS). While the ionic composition of the TDS may affect level of toxicity, the relationship between mining, elevated TDS, and impaired stream biota cannot be overlooked.	OSMRE acknowledges that the ionic composition of TDS can affect the level of toxicity and that the relationship between mining, elevated TDS, and impaired stream biota cannot be overlooked. However, OSMRE is stating that studies do not specify which activity of the mining process (i.e. blasting, spoil movement, coal stockpiling, reclamation practices, etc.) generates the contaminants that impact downstream resources, not which contaminants are contributing to the adverse ecological impacts. The text in section 4.2.1.3 has been clarified.
NA	EPA	Page 4-89, last paragraph: " ... high conductivity can be directly toxic to freshwater organisms ... " is correct but contradicts statement above regarding an absence of what particular aspect of mining generates adverse effects. U.S. EPA (2011), which establishes a conductivity benchmark for central Appalachia of 300 ~t S/cm, should also be cited and addressed in this section. We recommend that the Final ETS include additional and updated citations (see partial list below) to better demonstrate the body of scientific literature available on mining effects to aquatic and terrestrial systems.	This comment relates to U.S. EPA's potential misunderstanding of the statement in section 4.2.1.3 relating to which component of the mining operation generates adverse effects downstream. There is no contradiction in acknowledging that elevated conductivity is an environmental stressor and stating that studies do not specify what particular activity conducted in mining operations generates adverse effects. The text in section 4.2.1.3 has also been clarified. Based on U.S. EPA's recommendation, a reference to the 300 μS/cm conductivity benchmark has been included in the text.
NA	EPA	Page 4-93, paragraph 2: Include reference to the selenium criteria.	A citation to U.S. EPA, 2014, selenium criteria has been included in this paragraph.
NA	EPA	Page 4-334, footnote: U.S. EPA (2011) documents a scientifically valid, field-based benchmark for protection of aquatic life; we recommend that this be considered and addressed in the FEIS.	The conductivity benchmark provided by U.S. EPA, 2011, has been cited where possible.
NA	FWS	We recommend that OSMRE provide specific examples of	Our Knoxville Field Office (KFO) uses evaluation

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		detecting and then reversing an adverse trend in water quality early enough to meet pre-mining water quality. Such scenarios will assist the Regulatory Authorities (RA) and other reviewing agencies in applying the new regulations	thresholds on a routine basis. For example, in one case, KFO established an evaluation threshold of 1.0 mg/l for iron in a receiving stream. At some point after initiation of the mining operation, water monitoring data documented an exceedance of that threshold. A site visit found that the surface mining operation had encountered flooded abandoned underground mine workings; the permittee subsequently attempted to divert the flow from those workings to a pond for treatment. However, the diversion was not fully successful and some of the water entered the receiving stream without treatment. KFO required the permittee to construct a large three-cell wetland treatment system and divert all water from the underground workings to that system, which is successfully treating the water.
OSM-2010-0021-0696	Murray Energy Corporation	There are no established federal conductivity criteria, only benchmarks. Those benchmarks are deeply flawed. Accordingly, OSMRE's attempt to derive an enforceable conductivity standard is flawed and not supported by a rational basis. Moreover, federal selenium criteria are still in draft form and under review. Consequently, implementation of any selenium standards should wait until the federal criteria are finalized.	As described in the preamble to the proposed rule, 80 FR 44441 (July 27, 2015), the U.S. EPA has established an aquatic life benchmark of 300 microsiemens per centimeter (mS/cm) for electrical conductivity, based on a scientific determination that maintaining conductivity at or below this level should prevent the extirpation of 95 percent of invertebrate genera, such as mayflies, dragonflies, damselflies, and aquatic beetles, in central Appalachian streams. These standards can be found described in U.S. EPA. 2011. A Field-Based Aquatic Life Benchmark for Conductivity in Central Appalachian Streams (Final Report). Office of Research and Development, National Center for Environmental Assessment, Washington, DC. U.S. EPA/600/R-10/023F, p. 41. U.S. EPA states that this benchmark applies to parts of West Virginia and Kentucky and that it may be applicable to Ohio, Tennessee, Pennsylvania, Virginia, Alabama, and Maryland in Ecoregions 68, 69, and because the salt matrix and background (calcium and magnesium cations and sulfate and bicarbonate

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
			anions at circum-neutral pH) is expected to besimilar throughout those ecoregions. U.S. EPA further states that this benchmark also may be appropriate for other nearby regions, but that it may not apply when the relative concentrations of dissolved ions are different. As of July 13, 2016 the U.S. EPA has issued final aquatic life criterion for selenium. The EIS has been updated to refer to these criteria.
OSM-2010-0021-0696	Murray Energy Corporation	Finally, the assumptions stated in OSMRE's DEIS, that mines per se are degrading streams and affecting aquatic life is unmerited by OSMRE's Annual Reviews of mining activity in coalmining regions (see http://www.osmrc.gov/programs/oversight.shtm)	OSMRE inspections and other oversight activities in primacy states, including the annual evaluation reports, focus on the success of state regulatory authorities in achieving compliance with the approved regulatory program for the state.Directive REG-8, which establishes policy and procedures for the evaluation of state regulatory programs, specifies that the offsite impacts identified in annual evaluation reports do not include impacts from mining and reclamation that are not regulated or controlled by the state program. The evaluation reports include only those offsite impacts of coal mining operations that would constitute a violation of the approved regulatory program. Offsite impacts that would not be a violation of the approved program are not identified. In other words, the annual evaluation reports generally do not identify or discuss situations in which the existing regulations provide inadequate protection. Directive REG-8 provides discretionary authority for evaluations of impacts that are not prohibited by the regulatory program, but that authority may be exercised only if both we and the state agree to do so and if they are not characterized as offsite impacts. Historically, that discretionary authority has not been exercised.
OSM-2010-0021-0696	Murray Energy Corporation	Surface Water Overview Section 3.5.2.3, p. 3-139 The relative sensitivity of streams to disturbance based on rangeland management studies has little relevance to	Table 3.5-4 is provided to give the reader an understanding of stream sensitivities to disturbances in general, as part of the description of the affected environment. While

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		understanding disturbances based on mining activities. Rosgen (1994) acknowledges that some extrapolation is possible in the context of developing a classification scheme for other resource management practices; however, Rosgen (1994), Kasprak et al. (2015) Simon et al. (2007) and others point out that extrapolation and adopting a scheme derived from a different resource management practice is inappropriate. Consequently, the DEIS fails to provide an impact analysis that is specific and useful to understanding mining-related impacts.	the Rosgen method focuses on rangeland management there are similarities between this type of disturbance and others, for example sedimentation. The Rosgen method presented here does not form the basis of the analysis for impacts of mining as it would be implemented under each of the alternatives. The model mine analysis does not rely on this system of stream sensitivity characterizations.
OSM-2010-0021-0696	Murray Energy Corporation	Appalachian Basin Coal-Producing RegionSection 3.5.3.1, p. 3-150"Studies suggest the flow in streams draining coal-bearing rock is poorly sustained. . . . In areas of the Cumberland Plateau, low-flow data suggest that Pennsylvania sandstones, shales, and coals demonstrate significantly lower flow than Pre-Pennsylvanian Limestones and dolomites. It is unclear whether this finding is attributable to their storage potential or enhanced mining activity associated with the Pennsylvania geology."In this paragraph, OSMRE acknowledges that it is unknown whether lower groundwater flow is attributable to mining-related activity or natural storage conditions. This uncertainty calls into question the validity of OSMRE's discussions underlying Chapter 4 of the DEIS.	Thank you for the comment. The specific report (Hufschmidt et al. 1981) referred to in your comment acknowledged that its findings were a broad characterization of the hydrology of a large area. The report also acknowledged that analysis of hydrologic impacts from a specific mining operation would necessarily have to be supplemented by specific site hydrologic data for the mine vicinity and additional data on the specific proposed mining operation. The analysis of chapter 4 utilizes model mine scenarios, based on actual permit data to define conditions of thirteen typical mines in the seven regions, to generate conclusions regarding the potential hydrologic impacts from implementation of any of the alternatives. The analysis of Chapter 4 does not rely on the broad generalizations of the Hufschmidt et al. report.
OSM-2010-0021-0696	Murray Energy Corporation	The review presented in Section 3.6 includes a discussion of both direct mining-related air emissions and indirect emissions resulting from the combustion of coal in industrial and power generating emission units. The section then proceeds to analyze the impacts of these emissions on the attainment status of the various regions where coal mining occurs in the U.S. (Section 3.6.2 Air Quality by Coal-Producing Region). This analysis assumes that coal combustion emissions occur at the same location as coal mining. This is an incorrect and substantially inaccurate assumption that raises serious questions regarding the relevance of the analysis presented in this section. Coal is often transported significant distances (including export to	Section 3.6 provides a discussion of air quality resources as part of the description of the affected environment. It also provides general information on how emissions are released from mine sites and mining operations to provide a context for the later analysis of these issues related to each alternative. The analysis of the alternatives however, is done in section 4.2.4 of chapter 4. While the Alternatives would not directly affect operations at coal burning facilities, this section also includes a qualitative discussion of effects of coal burning on air quality to provide additional context and

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		other continents) to its point of combustion. In fact, according to an assessment performed by the National Renewable Energy Laboratory, the vast majority of greenhouse gas and criteria pollutant emissions associated with the coal life cycle occurs at power plants, not coal mines. In order to make a relevant analysis of impacts of the Proposed Rule on local National Ambient Air Quality Standards (NAAQS) attainment, this analysis must be redone accounting for coal combustion emissions at the point of combustion, not at the mine site.	information.
OSM-2010-0021-0696	Murray Energy Corporation	Air Quality by Coal-Producing RegionSection 3.6.2, pp. 3-211 to 3-231This section discusses the impacts on NAAQS nonattainment based on the proximity of coal mines to nonattainment areas. It further discusses the contribution of SC>2 emissions to particulate and SO2 nonattainment. This correlation is entirely inaccurate and misleading. Coal mines extract a naturally occurring material (coal) that generates SC>2 when combusted. Actual direct emissions of SC>2 at coal mine sites are trivial; SC>2 emissions from coal occur at the point of combustion, which is frequently in a different state, or even continent than the mine where the coal originated. This section should be revised or removed to correct this misleading analysis.	Section 3.6 provides a discussion of air quality resources as part of the description of the affected environment. It also provides general information on how emissions are released from mine sites and mining operations to provide a context for the later analysis of these issues related to each alternative. The analysis of the alternatives however, is done in section 4.2.4 of chapter 4. While the Alternatives would not directly affect operations at coal burning facilities, this section also includes a qualitative discussion of effects of coal burning on air quality to provide additional context and information.
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.8.3.2, pp. 3-250 to 3-259 It appears that OSMRE randomly selected the groups/taxa discussed in this section. For example, the DEIS provides a lengthy discussion regarding mussels, but only a few sentences on bats, with no discussion of how the latter is affected by mining. OSMRE should select groups for discussion based on the potential impact to the species' occurrence, status, characteristics, habitat, etc. from mining activities. The DEIS should discuss each group in relation to the Proposed Rule and its impacts on the species. Additionally, OSMRE should distinguish between the impacts to species caused by surface and underground mining	The discussion focuses on the taxa that are most likely to be impacted by the Proposed Action. The SPR would have minimal potential to change the level of effects on terrestrial species such as bats. The SPR contains requirements regarding reforestation but regardless, removal of vegetation prior to overburden removal would be required and terrestrial species in the area of vegetation removal would be impacted regardless of the alternative under consideration including the no action alternative. In contrast, the water quality implications of the alternatives have the potential for a greater degree of effect on aquatic species. Thus the discussion provides more detail on aquatic systems and resources than terrestrial ones. This is consistent with the requirements of NEPA to focus the

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
			discussion on the issues that are truly significant to the action in question. 40 CFR 1500.1(b).
OSM-2010-0021-0696	Murray Energy Corporation	OSMRE explains in Section 3 that the DEIS does not cover air resources. The discussion in Section 4, consequently, is inappropriate.	The comment is incorrect. Section 3.6 provides a discussion of air quality resources to comply with the requirement of NEPA for a description of the environment of the areas "to be affected or created by the alternatives under consideration" (40 CFR 1502.15).
OSM-2010-0021-0696	Murray Energy Corporation	In the discussion of the existing conditions, which is the model base condition and as such needs to be validated to demonstrate that it accurately represents the base conditions, there is little relevant information provided or references cited about western mines. One exception under Chemical Effects on Surface Waters (DEIS, at 4-50) is a reference cite to (Lowry et al., 1983) that indicates that acidity in western mines with higher alkalinity is "usually neutralized." Thus the one cited reference to western mine sites contradicts the purported water quality impacts that are said to be the intended target of the rule. Also see Table 4.2.1-6 (DEIS, at 4-66) which lists only references for eastern mine studies.	OSMRE agrees that acid or alkaline mine drainage has different or lesser impacts in western streams. As stated in the EIS, acid mine drainage "is relevant to mining nationwide, although not as prevalent in the western coalfields, where the geology, soils and hydrology provide high buffering capacity (alkalinity)." However, it is noted that heightened buffering capacity of western streams does not preclude water quality impacts that may be associated with mining. These impacts may include increased levels of total suspended solids, sulfates, and conductivity as discussed in Chapter 3 of the EIS.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.1.1, p. 4-49 This section addresses surface water effects of the No Action Alternative. The need for an action alternative should be based solely on current mining practices, as carried out under the No Action Alternative, not on historical mining operations.	OSMRE disagrees with the commenter's statement that the need for an action alternative should not be based on historical mining operations. In fact, as noted elsewhere by this commenter, OSMRE must consider all relevant past, ongoing, and reasonably foreseeable future impacts as part of the EIS analysis. This includes past effects associated with legacy mining activities.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.1.1, pp. 4-49 to 4-50 This section discusses the negative impacts of the currently regulated chemical effluents—acidity, alkalinity, conductivity, and total suspended solids—but does not discuss items in the expanded list or explain why not measuring them has a negative impact. Selenium and arsenic are discussed only later in the DEIS.	Additional discussion of chemical effects on surface waters has been added to section 4.2.1 in the FEIS.
OSM-2010-0021-0696	Murray Energy	Section 4.2.1.1, p. 4-50, first paragraph	The sentence in question is an introductory

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
	Corporation	Under existing regulations, mining continues to affect downstream water chemistry. This statement is very general and, while it may be true in specific instances, it is not true in general. There is no discussion of what small percentage of streams are subject to downstream water quality impacts.	statement, and while general, frames the discussion of the mining related effects on downstream water chemistry.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.1.1, pp. 4-52 to 4-53 This section introduces potential impacts to the groundwater resulting from both surface and underground coal mining operations. It should not be used in such a definitive context across all coal-producing regions in the U.S. OSMRE should emphasize the fact that every potential new project will have its own unique site characteristics. Each of the examples cited are field investigations of groundwater quality downgradient of surface coal mining operations. There is no mention of chemically impaired groundwater attributed to underground mining	Section 4.2.1.1 presents documented impacts of mining to surface water and groundwater. This section is dependent on published literature. The model mines analysis captures that different regions exhibit different sets of geologic conditions and associated suite of surface water and groundwater effects. Please see Master Responses on Regional Nature of Impact and Model Mines Analysis for more information.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.1.2, p. 4-56, Table 4.2.1-1, "Activities In or Near Streams, Including Excess Spoil and Coal Refuse" row "Limiting activities in or near intermittent and perennial streams should minimize the number and length of intermittent and perennial stream segments disturbed by mining, clarify that the regulatory authority can prohibit adverse impacts to perennial and intermittent stream segments of high environmental value, and ensure that operations promote enhancement of fish, wildlife, and related environmental values wherever and whenever practicable." Rarely are fill placement activities proposed or allowed in perennial streams, even intermittent streams are avoided most of the time. OSMRE exaggerates the positive effects of the rule.	The statement in 4.2.1.1 has been clarified to state that with respect to intermittent and perennial streams that are mined through during the course of mining operations, the CWA mitigation rule requires restoration. Compliance with these existing restoration standards will be required under the No Action Alternative.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.1.2, p. 4-56, Table 4.2.1-1, "Mining through Streams" row"Increase in miles of intermittent and perennial streams with restored hydrologic form and ecological function and increase in miles of ephemeral streams restored to hydrologic form after being mined through."The proposed limitations on mining through streams would have little effect in western jurisdictions where alluvial valley floor regulations and existing regulations already provide a similar level of protection (see Mont. Admin. R. 17.24.308).	The regulations associated with alluvial valley floors are limited by definition to operations in areas of the arid or semi-arid southwest with water availability sufficient for subirrigation or flood irrigation. The SPR makes no changes to the regulations pertaining to these operations, other than edits to the discussion of permit renewals involving alluvial valley floor variances within 774.15(c)(3) for simplification to adhere to plain language principles. No aspects of the

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
			alluvial valley fill regulations in 30 CFR 789.15 or 30 CFR Part 822 would be contradicted or superseded by the requirements of the SPR; neither do the requirements of the alluvial valley fill regulations make the SPR requirements unnecessary.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.1.2, pp. 4-60 to 4-61, last paragraph "Decreases in coal production in a given region would reduce the effects of coal mining on downstream water quality." OSMRE is mistaken on this point. Changes in coal production output have some ~ but not a significant -- correlation with effects on downstream water quality. Current land and water management practices by mining companies, regardless of the rate of coal production, largely influence downstream water quality.	OSMRE is not stating the degree to which downstream water quality would be impacted by the Action Alternatives in this sentence. The commenter states that coal production output has some relation to downstream water quality, which supports the statement in question in the text.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.1.5, p. 4-77 Under Alternative 1 (No Action Alternative), persistent effects from acid mine drainage are predicted. However, acid mine drainage is addressed under current regulations making such an outcome unlikely.	The text has been clarified to state that no further regulations or corrective measures in addition to those already in place would be implemented.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.1.5, p. 4-77 "Under the No Action Alternative, no changes in mining practices would occur and current water quality issues would likely persist. Subsection 4.2.1.1 above describes these issues in detail. They include pH impacts from acid mine drainage; elevated concentrations of iron, aluminum, manganese, and sulfate; sedimentation in the water column; flow alteration and stream elimination as a result of mining through streams and spoil management practices; drawdown of groundwater levels; and degradation of groundwater through increased concentrations of sulfate, iron, and other pollutants." OSMRE's statements imply that all coal mines are the same with regard to water quality and geology. In fact, coal mines, water quality, and geology vary significantly from region to region. NPDES regulations already in existence are being used to address potential issues.	The text has been clarified to state that under this alternative (i.e., No Action Alternative) no changes in mining practices would occur and current water quality issues associated with each mining system would likely persist. The clarifications communicate that conditions are not the same across all mining systems.
OSM-2010-0021-0696	Murray Energy Corporation	Biological Resources Section 4.2.2, p. 4-83 This section appears to advance the idea that no adverse effects are tolerable. This is unrealistic for coal mining or any other	The purpose of the proposed SPR is to reduce the adverse effects of coal mining on streams, and OSMRE states in section 4.2.2.2 that "The

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		industrial endeavor.	Action Alternatives include elements intended to reduce the adverse effect of coal mining activities on biological resources". Section 4.2.2 does not imply that any adverse effects are intolerable, but rather summarizes and analyzes the impacts of coal mining on biological resources given the current state of the science.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.2.1, p. 4-88 "Effects to the thermal regime (the fluctuation of water temperature throughout the year" "Effects to the flow regime (the baseline flow, or minimum flow of water throughout the year, and the pulses of water due to significant precipitation events) " No further explanation is provided for the first point, but of course, temperatures fluctuate throughout the year regardless of whether mining occurs. The second bullet point notes adverse effects to the flow regime. However, this appears to be based on the mistaken notion that mining necessarily increases flood potential, when the opposite is true in many cases. Additionally, valley fills in the Appalachian Region have been demonstrated to result in more consistent baseflow downstream of the fill.	Effects to temperature are often regulated under State CWA section 402 permits to address effects of higher temperature water on sensitive or indicator species. The commenter is mischaracterizing the second bullet regarding effects to the flow regime. OSMRE acknowledges that mining may often reduce the peak flows and total runoff from storm events and baseflow to streams, and the quoted portion of the text is a reference to the effect this has on stream biota.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.2.1, p. 4-94, first full paragraph "As a result, these structures alter the timing and amount of water that reaches streams, which in turn adversely impacts downstream habitats..." This conclusion ignores the potential habitat Benefits of water retention and delayed release, particularly for flashy arid/semiarid ephemeral streams where flows may only last hours, and delayed release could maintain vegetation in or adjacent to the channel for a longer period of time.	No documentation could be found to support the potential benefit suggested by the commenter.
OSM-2010-0021-0696	Murray Energy Corporation	OSMRE makes several claims throughout the DEIS, including [Section 4.2.2.1, p. 4-95, first paragraph], that a reforestation requirement with minimal discontinuity is essential to discouraging disruption, including the possibility for extinction, of species. However, OSMRE does not provide evidence where mine reclamation has endangered or caused the loss of species because of forest fragmentation or reclamation associated with mining. OSMRE should provide a	As described in Section 4.2.2.1, mining requires land clearing and temporary displacement of habitats, and creates discontinuity between different patches of remaining habitat. Continuing to promote discontinuity between forest patches will result in habitat fragmentation and edge effects. While a complete accounting of the effects of coal

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		more thorough analysis. The absence of objective information supporting these claims undermines the soundness of OSMRE's assertions. OSMRE should clarify how it arrives at conclusions that the No Action Alternative is less desirable than other options.	mining related forest habitat loss and fragmentation on species populations does not exist, Section 4.2.2.1 has been edited to provide examples of documented impacts. In particular, we note the effects of coal mines on forest habitat availability and populations of the cerulean warbler.
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.8.2.2, p. 3-246 "The remaining list includes 60 species with designated critical habitat. The critical habitat of 39 of these 60 species occurs partially or entirely within the coal resources areas studied in this EIS. As shown in appendix F, Table F-2 Critical Habitat Overlap with coal regions, 100% of the critical habitat for the Laurel dace (Chrosomus saylori) occurs in areas with mineable coal." References to Appendix F Critical Habitat Overlap with Coal Regions are inadequate for identifying species' critical habitat for a specific region because the appendix is a summary for all regions collectively. OSMRE should separate the appendix into listed species by cover type by region.	The level of detail in the DEIS was sufficient but has been updated. The DEIS analyzed regional distributions of critical habitat, as well as the distribution of forest cover. Additional detail on species and habitats by region are contained within the Biological Assessment and Biological Opinion for the Stream Protection Rule.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.3.2.7, pp. 4-255 to 4-260 OSMRE presents the results of "analysis" for each alternative but provides no additional information on how the analysis was performed. It is unclear to what extent the results are based on evaluation and interpretation of actual data and how much is subjectively based on the personal judgment or opinions of the assessor(s).	The commenter is referring to EIS section on impacts to Land Use. As described, this analysis uses data on mining through streams; activities in or near streams (including excess spoil and coal refuse); AOC variances; surface configuration; revegetation, topsoil management, and reforestation; and fish and wildlife protection and enhancement.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.3.4.1, p. 4-288 Discussion of a single watershed is insufficient to characterize the range of selenium concentrations resulting from coal mining nationwide. OSMRE should provide a broader discussion that covers the wide range of selenium concentrations that have been documented in various coal mining areas throughout the U.S. and Canada.	Additional citations have been added to the Effects of Selenium on Public Health in section 4.3.4.1 that expand upon and support the original sources cited.
OSM-2010-0021-0696	Murray Energy Corporation	Section ES.I, p. ES-1"Scientific studies published since the adoption in 1983 of our principal regulations have indicated that surface coal mining operations continue to have significant negative impacts on streams, fish, and wildlife despite the enactment of SMCRA and the federal regulations implementing that law."This statement, which only mentions "surface coal mining operations," does not support	As discussed on page 1-3 of the DEIS, SMCRA defines surface coal mining and reclamation operations to include the surface effects of underground mining. 30 U.S.C. 1291. The environmental implications of the alternatives, including effects of the new requirements, on the surface effects of underground mining have

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		new or expanded regulation of underground mining. Moreover, as proposed, the rule would likely cause additional environmental degradation through requirements that result in slower reclamation (i.e., from needing to rework ditches multiple times), more drilling rigs, more site activity, more time onsite, increased haul distances, more storage piles, complication of an already complicated process, and longer delays in the permitting process, and which will increase overall disturbance time, eliminate sediment basins in intermittent streams resulting in additional disturbance and ditching, and increase noise.	been analyzed and are presented in the EIS and RIA.
OSM-2010-0021-0696	Murray Energy Corporation	In addition, since reclamation activities will be slowed, temporal effects to the environment will be extended (e.g., methane emissions will be increased as a result of a slowed operation). All of these additional impacts would have significant negative effects on streams, fish and wildlife.	OSMRE does not anticipate that the rule will result in slowing reclamation activities.
OSM-2010-0021-0696	Murray Energy Corporation	Hydrologic balance encompasses the dynamic relationship among precipitation, runoff, evaporation, and changes in ground and surface water storage. The cause-effect relationships between nutrient stressors and biological responses, from which the designated use criteria are derived, can be highly uncertain (Reckhow et al., 2005; Suplee et al., 2007; Stevenson et al., 2008; Kenney et al., 2009). The uncertainty of this cause-effect relationship results in an inability to correlate the effects of mining on the hydraulic balance, or the effects of the hydraulic balance on the environment.	Although there are uncertainties regarding the cause-effect relationship between water quality criteria concentrations and their specific effect on a given population of stream biota, there is extensive research, especially related to aquatic life water quality standards, outlining what LD50's and other biological indicators for sensitive and indicator species. The new aquatic life criterion for selenium is discussed in section 4.3.3.2 of the EIS.
OSM-2010-0021-0696	Murray Energy Corporation	Section 1.1.1, p. 1-11"Despite the enactment of SMCRA and the promulgation of federal regulations implementing the statute, surface coal mining operations continue to have negative effects on streams, fish, and wildlife. These conditions are documented in the literature surveys and studies discussed in Chapter 4."Pfannenstiel and Wendt (2002) cite 15 scientific studies published since the implementation of SMCRA that reflect advancements from research, application of new and improved technologies, mine-specific experience, and innovation that have reduced negative impacts on streams, fish, and wildlife. Pfannenstiel and Wendt. 2002. Twenty-plus years after SMCRA: Reflecting on the results. National Meeting of the American Society of Mining and Reclamation, Lexington KY, June 9-13, 2002. Published by ASMR, Lexington, KY 40502.	The text in question is not claiming that there have not been advances made in reclamation science. Further, OSMRE acknowledges the progress made toward better reclamation practices since the inception of SMCRA. Review of the 15 references mentioned in the comment reveals that impacts related to mining still occur despite the advancements that have occurred.

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
OSM-2010-0021-0696	Murray Energy Corporation	Surface Water Overview Section 3.5.2.3, p. 3-139 "The predictions were derived from rangeland management studies but are applicable to other kinds of disturbances such as silviculture and surface mining (Rosgen, 1994; Rosgen, 1996)." OSMRE should explain whether these predictions are applicable to all regions. For example, it is unclear whether these predictions could be extrapolated to the Appalachian Basin Region.	While the Rosgen method focuses on rangeland management there are similarities between this type of disturbance and others, and the author explains that it is a theoretically derived classification scheme that is not intended to match observations of any specific water, within any specific region. Instead its purpose is to provide a useful classification methodology for extrapolation purposes, restoration designs, and prediction based on generally representative physical characteristics of a river.
OSM-2010-0021-0696	Murray Energy Corporation	Introduction and Background Section 3.6.1, p. 3-202 Later sections of the DEIS recognize that SMCRA does not provide a mechanism or authority for OSMRE to regulate air emissions. Consequently, OSMRE's rationale and purpose behind this discussion of emissions of commonly regulated substances associated with the combustion of motor fuels is unclear, and it should be removed from the DEIS.	As discussed in section 4.2.4 OSMRE is limited in its ability to regulate air quality. Air emissions permits for coal mines fall under the authority of the Clean Air Act (CAA) and are not issued under SMCRA. The decision discussed in In re Permanent Surface Min. Regulation Litig. I, Round II, 1980 U.S. Dist. LEXIS 17660 at *43-44 (D.D.C., May 16, 1980), 19 Env't Rep. Cas. (BNA) 1477, clarifies that OSMRE does not have jurisdiction over industrial emissions, and that its jurisdiction is limited to air pollution attendant to wind and water erosion (e.g., exposing soil to wind causing particulates to become airborne). The decision clarifies that all other mining-related emissions are generally regulated under the CAA and not SMCRA. However the discussion of Section 4.2.4 examines air quality as a resource within the human environment, focusing on the specific components that coal mining operations can influence, and does not limit the discussion to what OSMRE is specifically authorized to regulate (i.e., erosion-related air pollution). This provides the required basis (40 CFR 1502.16) for a scientific and analytic comparison between the Alternatives.
OSM-2010-0021-0696	Murray Energy Corporation	Clean Air Act Regulatory FrameworkSection 3.6.1.1, p. 3-206"It should be noted that diesel engines used in underground mining equipment are exempt from these requirements as diesel emissions and air quality from such	Thank you for the comment. Edits have been made to Section 3.6.1.1 to clarify the MSHA regulations that apply.

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		engines are regulated by the Mine Safety and Health Administration (MSHA)."This statement implies that emissions from underground mining equipment are not as stringently regulated as non-road equipment. In fact, the opposite is true. In order to achieve MSHA occupational exposure standards in an underground mining environment, tailpipe emission control technology for underground diesel-powered mobile equipment has far surpassed and preceded emission reductions achieved by non-road diesel engines. Tailpipe emission controls such as ceramic tailpipe particulate filters and NOX controls were pioneered on underground mining equipment and have yet to be applied to non-road equipment. OSMRE should correct the misleading characterization contained in the above referenced section of the DEIS.	
OSM-2010-0021-0696	Murray Energy Corporation	Federally Protected and Regulated Species Section 3.8.2.2, p. 3-246 "Another recent issue of concern for species that overlap mining areas is white-nose syndrome, a syndrome caused by the white fungus (Pseudogymnoascus destructans), which is causing fatalities in hibernating bats from the northeastern to the central U.S. The USGS reports that northeastern U.S. bat populations have declined approximately 80% since the emergence of the disease (USGS, 2015)." OSMRE should clarify the relevance of this information to mining or remove the statement entirely. To date, no link has been established between mining activity and white-nose syndrome in bats (Coleman and Reichard, 2014). Providing this sort of information in the DEIS does nothing but imply that white-nose syndrome, a serious threat to bat populations, is the result of coal mining activities.	Section 3.8.2.2 provides a discussion of resources in the area of effect, as required under 40 CFR 1502.15 to "describe the environment of the area(s) to be affected or created by the alternatives under consideration."
OSM-2010-0021-0696	Murray Energy Corporation	Alternatives 5, 6, and 7 require a 100-foot riparian buffer for all streams, similar to Alternative 2. However, because the requirements under Alternatives 5 and 7 apply only under specific circumstances, the associated Benefits to riparian and aquatic biological communities would be more limited than under Alternative 2, which is applicable to all surface coal mining operations. Likewise, all Alternative 6 elements apply only to activities in the 100-foot riparian corridor of intermittent or perennial streams. OSMRE should clarify the apparent contradiction in stream protection for Alternative 6. OSMRE states here that 100-foot buffers will	The text has been clarified (see section 4.2.2.5). Under alternative 6 if an operation were to occur partially or entirely within the 100-foot riparian corridor of an intermittent and perennial stream a 100-foot riparian buffer would be required around any impacted streams within that corridor regardless of type. For example, alternative 6 would require a 100-foot riparian buffer around the ephemeral stream segments occurring within 100 feet in any direction (including upstream) from impacted

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		be required for all stream types.	intermittent or perennial stream segments. This has been clarified in Section 4.2.2.5.
OSM-2010-0021-0696	Murray Energy Corporation	*Coal mining alters the landscape by removing coal resources and changing the configuration and physical properties of rock and other earthen materials overlying the coal seam. Depending on the original topography, the thickness of the coal seam, the relative thickness of overburden, and mining method, significant changes in topography can result.* These effects are not limited to coal mining. Actions are taken every day as part of commercial, residential, and public land development projects that affect far greater areas than all mining in the U.S. combined. Also, this statement implies that all coal mining is surface, open-pit mining, when most coal mining is not.	OSMRE recognizes that impacts to natural resources occur in response to other activities in addition to coal mining. Trends in these other activities are discussed in the Cumulative Impacts section of the EIS. However, the focus of the impacts analysis is on the impacts of the SPR implementation on natural resources.
OSM-2010-0021-0696	Murray Energy Corporation	*Underground mining also can dewater streams or diminish flows by fracturing strata that support perched aquifers or by draining aquifers to facilitate mining.* OSMRE suggests that there is always a direct interaction between surface water and groundwater systems. Groundwater and surface water bodies are not always connected, and not all waterbearing units, especially those characterized as perched, are viable or significant water sources.	Mining activities can affect both the quantity and direction of groundwater flow, however, OSMRE is not implying that this is always the case. Water infiltration contributes to groundwater, and coal mining and reclamation activities can change overland flow and the amount of water that infiltrates the surface to ultimately recharge the groundwater system.
OSM-2010-0021-0696	Murray Energy Corporation	*Section 4.2.3.1, p. 4-133* *Surface mining completely alters the geologic structure above the lowest coal seam mined in that previously discrete strata of rock and soil, each stratum with its own distinctive characteristics, are converted to a more or less uniform fragmented mixture of rubble.* Any land development project will alter the surface geology to some degree. Surface mining is only a fraction of the nation's current and planned public and private land development activities.	OSMRE recognizes that impacts to natural resources occur in response to other activities in addition to coal mining. Trends in these other activities are discussed in the Cumulative Impacts section of the EIS. However, the focus of the impacts analysis is on the impacts of the SPR implementation on natural resources.
OSM-2010-0021-0696	Murray Energy Corporation	*Section 4.2.3.2, p. 4-134 None of the alternatives under consideration for the Protection of the Hydrologic Balance functional group would have any direct impacts on topography, geology, or soils.* OSMRE suggests that the hydrologic balance will stay intact only when there are no changes to the surface topography or soils. This is incorrect. Changes in natural precipitation, surface vegetation, and upstream changes to land use unrelated to mining activity have a large influence on the hydrological balance. For	OSMRE recognizes that impacts to natural resources occur in response to other activities in addition to coal mining. Trends in these other activities are discussed in the Cumulative Impacts section of the EIS. However, the focus of the impacts analysis is on the impacts of the SPR implementation on natural resources.

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		example, Gerten et al. (2004) and Andreassian (2004) describe the importance of vegetation and the natural evolution of changes in forestation and land use on the hydrologic balance.	
OSM-2010-0021-0696	Murray Energy Corporation	*Section 4.3.4.1, p. 4-289, Figure 4.3.4-2* *Figure title: Selenium concentrations fag/L or parts-per-billion) measured in coal mine discharges and surface waters of the Mud River ecosystem, West Virginia, relative to levels that can bioaccumulate and become toxic to fish.* The figure shows a chart from Lemly (2008) of selenium concentrations measured in the Mud River ecosystem and mine discharge relative to "toxic" levels for fish. OSMRE states that selenium in West Virginia is the most extensively studied in the U.S., and the Lemly (2008) study of Mud River watershed was selected as a case study. However, the water concentrations shown for the river and reservoir are based on small sample sizes ranging from n=l to n=36, which is insufficient to draw conclusions for an entire watershed and ecosystem. One example does not suffice in demonstrating selenium impacts on coal mining nationwide.	The studies by Presser and Luoma, 2010, and Presser, 2013, further support Lemly, 2008. Presser, 2013, documents other historical data sets and provides new data on selenium concentrations in stream water over a wider geographic range in West Virginia. These new data support the selenium concentrations observed by Lemly, 2008. The newer studies also provide mechanisms for bioaccumulation in ecosystem-based food webs, which clearly demonstrate the risk of bioaccumulation associated with selenium concentrations common to waterways downstream from coal mining activities. Further, given the increased awareness of how rapidly selenium can bioaccumlate in local foodwebs at low streamwater concentrations, U.S. EPA (U.S. EPA, 2014) has recommended that selenium concentrations in faunal tissue be used as a primary indicator of selenium toxicity in waterways.
OSM-2010-0021-0696	Murray Energy Corporation	Section B.2, p. B-l Barbour et al. (1999) is a methods document, and not a comprehensive research effort, yet it is continually cited by OSMRE with respect to key concepts and assumptions. OSMRE should identify any other studies supporting the metrics and methods proposed specifically for applicability to mining sites.	Barbour et al. (1999) is cited a total of 10 times in appendix B of the EIS, but these instances include several that are using the reference to help explain well accepted concepts related to assessment against reference conditions. The rule itself provides discretion to the SMCRA regulatory authorities to determine the appropriate metrics and methods for the specific condition; see the preamble to the rule. Therefore the reliance on Barbour et al. (1999) in the appendix of the EIS is nonconsequential to the analysis of the implications of the alternatives.
OSM-2010-0021-0696	Murray Energy Corporation	Section B.2, pp. B-l to B-7OSMRE provides no discussion of baseline monitoring, which is the subject of this appendix. Using ecoregion reference for comparison is fine for that point in time, but sampling the stream prior to impact and	Thank you for your comment. The subject of Appendix B is stream biological assessment. The text provides an overview of criteria and metrics used in typical bioassessment methods.

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		then during or following impact does not provide sufficient cause-and-effect relationships between a specified activity, given the variables that can occur in both the baseline year and subsequent years. Variables such as weather, drought, floods, hurricanes, tornadoes, snowstorms, etc., can cause as much change as a specific activity. Sampling in different seasons can also result in different metric scores, and not all metrics are responsive to a specific perturbation.	In response to comments on the proposed rule, OSMRE has had extensive conversations with the Army Corps of Engineers and the U.S. EPA on biological baseline data collection and monitoring for aquatic resources and for demonstration of ecological function. Please refer to the final rule and preamble for detailed discussions of these topics.
OSM-2010-0021-0696	Murray Energy Corporation	*Section B.2, pp. B-l to B-2, last paragraph* *Each metric is a characteristic of the organism(s) that changes in a predictable way to disturbance.* This is rarely true, and much less demonstrated even on a case-by-case basis for mining sites. These methods were developed based on organic enrichment and siltation effects not necessarily relevant for mine sites.	We disagree with commenter's suggestion that these methods are not relevant for mine related disturbance. Siltation is a possible result of mining disturbance. The U.S. EPA's Rapid Bioassessment Protocols have been used nationwide including within areas of active mining. Established biocriteria are based upon the expected biological community of a reference stream. The reference stream by definition is undisturbed and provides the bar by which the response of the organism in the disturbed site is measured.
OSM-2010-0021-0696	Murray Energy Corporation	*Section B.2.2, p. B-3, second and third paragraphs Examples of taxa richness metrics include total species richness and the number of species found within the insect orders Ephemeroptera, Plecoptera, and Trichoptera (EPT), i.e., the number of mayfly, stonefly, and caddisfly species. Other examples of relative abundance metrics include Percent Top Dominant Species and Percent Ephemeroptera.* OSMRE should replace the word "species" with "taxa." Taxa richness means the number of taxa in a given sample, which can be the number of families, genera, or species, or a combination of these if some individuals cannot all be identified to the same taxonomic level.	We agree that measurements of taxa richness and relative abundance are not based solely on species, and that certain individuals may only easily be identified to taxonomic levels other than species. However, the text provides these only as examples and these examples are not intended to be an all-inclusive list of metrics for either taxa richness or relative abundance.
OSM-2010-0021-0696	Murray Energy Corporation	Section B.2.2, p. B-4, Table B-l, HBI (Hilsenhoff Biotic Index) The North Carolina Biotic Index (NCBI) is used as much, if not more often, than HBI. NCBI should be included as an example.	No change is necessary in response to this comment. Table B-1 provides a non-inclusive list of commonly used, nationally applicable metrics used for macroinvertebrates. Examples are provided to illustrate the concepts of each type of measure but we recognize that the table does not include every commonly used system, including the North Carolina Biotic Index as pointed out in the comment.
OSM-2010-0021-0696	Murray Energy	*Section B.2.2, p. B-5, Table B-l, "Tolerances Measures" row*	We agree that the number of intolerant taxa is

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
	Corporation	*Number of Intolerant Taxa: Number of macroinvertebrate families with tolerance values of three or less* OSMRE should replace the word "families" with "taxa." Taxa richness means the number of taxa in a given sample, which can be the number of families, genera, or species, or a combination of these if some individuals cannot all be identified to the same taxonomic level.	not limited to families, genera, or species alone. While this is given as an example, we understand that this may not provide sufficient clarity; therefore, we have revised the explanation as follows: "Number of macroinvertebrate families, genera, species, or combination of these, with tolerance values of three or less."
OSM-2010-0021-0696	Murray Energy Corporation	Section B.2.2, p. B-5, Table B-IOSMRE should add another category as follows: "Number of Tolerant Taxa: Number of macroinvertebrate taxa with tolerance values of seven or higher."	We agree with the commenter that the Number of Tolerant Taxa should be included within the table to be consistent with the layout of intolerant taxa. Table B-1 has been updated.
OSM-2010-0021-0696	Murray Energy Corporation	*Section C.1.3, p. C-2, third paragraph* *Levick et al. (2008) discussed the functions of ephemeral and intermittent streams...* Levick et al. (2008) is cited many times as support for the importance and functions of ephemeral and intermittent streams in arid and semiarid regions. OSMRE should identify other studies that reached similar conclusions, particularly for streams in higher rainfall areas.	As identified in the preamble to the proposed rule (See 80 FR 44451, published July 27, 2015) U.S. EPA recently completed a literature review of the importance of headwater streams and published a report summarizing the findings of more than 1,200 peer reviewed studies. The report is titled "U.S. Environmental Protection Agency, Connectivity of Streams and Wetlands to Downstream Waters: A Review and Synthesis of the Scientific Evidence (Final Report). Office of Research and Development, National Center for Environmental Assessment, Washington, DC U.S. EPA/ 600/R-14/47F (2015). The report is available in its original location at http://cfpub.epa.gov/ncea/cfm/recordisplay.cfm?deid=296414, and has also been uploaded to regulations.gov along with other noncopyrighted supporting documents for the SPR. The SPR docket at regulations.gov can be accessed at https://www.regulations.gov/#!documentDetail;D=OSM-2010-0018-0001.
OSM-2010-0021-0696	Murray Energy Corporation	*Section C.I .3, p. C-2, third paragraph* *In arid and semi-arid regions, the variability of the hydrological regime is the key determinant of both plant community structure in time and space and the types of plants and wildlife present.* Most of the mining regions are not in arid or semiarid regions. OSMRE should include a discussion of ephemeral and intermittent streams representative of all the regions discussed in the Proposed Rule.	The comment quotes text from one sentence of a passage from Levick et al. (2008) that is providing information on how the streams of arid and semi-arid streams differ from the streams in areas already described (i.e. streams in non-arid or semi-arid regions). The passage does not exclusively focus on streams in arid and semi-arid regions and neither does the DEIS.

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
OSM-2010-0021-0696	Murray Energy Corporation	*Section C.I.6, p. C-3, first paragraph* *During hyporheic flow, stream water and groundwater mix in the beds and banks of ephemeral, intermittent, and perennial streams and sometimes in regions surrounding stream channels (Findlay, 1995; Levick et al, 2003).* Neither of these two publications discusses ephemeral streams	The quoted text comes directly from page 7 of Levic et al, 2003. The reference to Findlay appears therefore to be unnecessary for this specific statement and has been deleted.
OSM-2010-0021-0696	Murray Energy Corporation	*Section C.I.7.1, p. C-7, second paragraphOnce flow becomes channelized, the ability to trap sediment is significantly reduced (Karr and Schlosser, 1978; Dillaha et al, 1989; Osborne and Kovacic, 1993; Daniels and Gilliam, 1996).* OSMRE should list sediment reductions from these studies for comparison	Thank you for the comment. After thorough consideration we have decided not to make the suggested change. The quantity of sediments trapped in each study would depend on a multitude of factors and therefore a direct comparison between the findings of the studies would require a lengthy discussion of the methodology and variables relevant to each study, and some amount of normalization across the findings. For the intended purpose of the paragraph in this appendix of the DEIS, which is to merely inform the reader of the basic finding that stream form affects stream deposition, this level of detail is unnecessary. For example, Karr and Schlosser (1978) found that the effects of vegetation on nutrient and sediment transport was dependent on several variables including water depth relative to vegetation height, length and slope of the vegetated area, vegetation characteristics, size distribution of incoming sediments, application rate of water, overall slope and the slope length before water reaches the vegetation.
OSM-2010-0021-0696	Murray Energy Corporation	*Section C.I.8, p. C-I 1, first paragraph* *In a study of intermittent and perennial streams in Alabama, macroinvertebrate assemblages of normally intermittent streams did not differ greatly from those of nearby permanent or perennial streams (Feminella, 1996).* Feminella studied 6 small streams for 2 years, all of which were intermittent (normally intermittent, rarely intermittent, occasionally intermittent), and found that 75% of the 171 taxa were common in all 3 types of intermittent streams. He also found that "year-to-year differences in assemblages within single streams appeared as great as differences between streams of contrasting permanence within a given year." So even with no detrimental inputs	The referenced text is discussing the Feminella research conclusions that showed similarities in organisms present in intermittent streams in comparison to perennial streams. The text did not assert that this research examined differences in streams as a result of impacts. Variability between sampling periods, and the impact that variability would have in determining if material damage to the hydrologic balance had occurred, has been accounted for in the final rule.

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		into these streams, there were differences within the same stream between the years.	
OSM-2010-0021-0696	Murray Energy Corporation	*Section C.I.9, p. C-13, first paragraph* *U.S. EPA et al. (2003) provided a detailed description of the River Continuum Concept developed by Vannote et al. (1980); that description is included here because it is relevant to the streams and rivers distributed throughout the coal regions of the U.S.* The river continuum concept relates to much larger systems than the small streams on mining sites. Such dynamic processes and scales are not relevant, and the organisms resident to such small streams are suited to these less dynamic systems. OSMRE should clarify whether it is intended that all processes related to river continuum concept be considered or evaluated in reclaiming such small streams.	Appendix C is provided for information purposes to elaborate on concepts of aquatic systems that can and do occur in coal mining regions. OSMRE does not intend that the inclusion of this information be construed as a requirement to consider or evaluate all streams in accordance with the concept.
OSM-2010-0021-0696	Murray Energy Corporation	*Section C.2, p. C-19, first paragraphLentic aquatic systems are defined as non-flowing water bodies such as natural lakes and ponds or artificial impoundments such as a reservoir. Lentic systems are also referred to as lacustrine habitats, which may include palustrine habitats as described below. Lentic water bodies can be permanently flooded, intermittent (e.g., playa lakes), or have a tidal influence where ocean derived salinities are below 0.5 percent (Cowardin et al., 1979). Some lentic systems may be fresh water bodies, while others have varying levels of salinity (e.g., Great Salt Lake).* OSMRE should clarify the relevance of discussing standing waters and lakes.	Appendix C is an overview of all aquatic systems occurring in coal mining regions. Lentic systems occur within coal mining regions.
OSM-2010-0021-0696	Murray Energy Corporation	Effects of the Current Regulatory Environment (the No Action Alternative) Section 4.2.2.1, p. 4-93 This statement ignores the fact that replacing the physical habitat is a large part of restoring the biological community, and particularly for western ephemeral streams, there may be little or no aquatic biological community present.	OSMRE acknowledges that stream habitat and buffer restoration provides the basis for biological community development. However, Northington et al., 2011, indicates that recovery of biological characteristics does not always occur. These statements do not refute that western ephemeral streams may demonstrate a different biological community.
OSM-2010-0021-0696	Murray Energy Corporation	Effects of the Current Regulatory Environment (the No Action Alternative) Section 4.2.2.1, p. 4-94, first full paragraph Current and future regulations will require structures for erosion prevention and sediment control, which are likely to be part of an NPDES permit. By restricting or eliminating	The comment is incorrect. The alternatives do not eliminate or excessively restrict placement of sediment ponds. To the contrary, the final rule merely requires at Paragraph (c)(1) of 816.45 that permittees locate sediment ponds as near as possible to the disturbed area and

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		detention basins and sediment ponds, OSMRE is effectively encouraging more soil erosion and sedimentation during rainfall events during active mining operations. Further, the entire analysis of land disturbance is focused and relevant only to surface mining conditions.	outside perennial or intermittent stream channels unless the regulatory authority approves of the location in accordance with sections 780.28 and 816.57(h). In all cases, operators must construct sediment ponds as closely as possible to the downstream limit of the disturbed areas they serve. These requirements minimize, to the extent possible, adverse impacts to streams, particularly intermittent and perennial streams.
OSM-2010-0021-0696	Murray Energy Corporation	Action Alternatives and Potential Effects on Biological Resources Section 4.2.2.2, p. 4-97, first paragraph OSMRE is incorrect. If stable stream channels are constructed properly, it would be fairly easy and cost-effective to ensure that benthic invertebrates are reintroduced successfully.	The commenter understates the complexity of the restoring a healthy biological community. While it may be true that restoring benthic invertebrates would be cost-effective, the commenter fails to acknowledge that benthic invertebrates represent a limited range in food webs of stream systems. Restoring true ecological function to a stream system would also include returning primary production to support the introduced benthic invertebrates and higher order consumers, such as those that prey on benthic invertebrates. The complexity of the trophic ladder bears further questions relating to appropriate nutrient input to stimulate primary production and the correct mix and abundance of higher order consumers such that lower trophic levels remain viable.
OSM-2010-0021-0696	Murray Energy Corporation	Impacts of the No Action Alternative on Water Resources; Surface Water andGroundwater EffectsSection 4.2.1.1, p. 4-49OSMRE allows for exceptions to the Proposed Rule for remining to occur to improve water quality; however, here, OSMRE states all mining has negative impacts with respect to water quality and quantity.	Thank you for the comment. The text is clear and requires no change. The text acknowledges that both surface and underground mining operations have the potential to adversely affect surface water quality; the statement is not definitive, it does not say that all mining results in impacts. Additionally the page speaks about activities that are an unavoidable consequence of mining as a result of the nature of the activity including removing surface disturbance and vegetation removal associated with construction of mine related features or to remove the coal itself. These factors would also be associated with remining activities to some extent but do not negate the potential

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
			site specific, net Benefits of remining.
OSM-2010-0021-0696	Murray Energy Corporation	Impacts of the No Action Alternative on Water Resources: Surface Water and Groundwater Effects Section 4.2.1.1, pp. 4-49 to 4-50 This section discusses the negative impacts of the currently regulated chemical effluents—acidity, alkalinity, conductivity, and total suspended solids—but does not discuss items in the expanded list or explain why not measuring them has a negative impact. Selenium and arsenic are discussed only later in the DEIS.	The discussion of 'Chemical Effects on Surface Waters' and 'Documented Impacts Related to Activities in or Near Streams' sections of Chapter 4.2.1.1 have been updated to include more discussion of selenium as an important biologic stressor. Further, the discussion now includes information on the recently developed conductivity thresholds presented in U.S. EPA, 2011.
OSM-2010-0021-0696	Murray Energy Corporation	Impacts of the No Action Alternative on Water Resources: Chemical Effects on Surface Waters Section 4.2.1.1, p. 4-50, first paragraph OSMRE presumes that all mining activities in all regions have the ability to release these specific elements, when, in fact, most mines do not exceed NPDES limits.	The Clean Water Act is not as comprehensive as SMCRA with respect to protection of the hydrologic balance. The Clean Water Act does not require establishment of a premining baseline and it only requires monitoring of point-source discharges. SMCRA requires that permit applications include baseline information so that the potential impacts of mining can be assessed at the time of permit application and so that impacts that occur during mining and reclamation can be readily identified and evaluated. SMCRA also requires monitoring of both the quality and quantity of surface water and groundwater, as well as monitoring sites located above and below the mine site. Therefore, deferral to state Clean Water Act authorities would not achieve the same results as the stream protection rule.
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.8.3.3, pp. 3-253 to 3-254 "Based on the important role that crayfish play in the stream food web, any disturbance to crayfish abundance may have a negative impact on the stream ecosystem (Seiler and Turner, 2004)."If, as stated in the DEIS, "any disturbance to crayfish abundance may have a negative impact," it is unlikely that crayfish populations (abundance) would increase six-fold in response to acidification, an obvious concern in mining areas. The unexpected relationship between crayfish abundance and acidic conditions, and the higher crayfish abundance in intermittent streams point to the fact that determining causality between physical/chemical conditions and biological health in a stream can be very difficult and	The commenter has taken the quoted text out of context. The text in its entirety is merely making the point that crayfish are important components of the ecosystem and that reduced crayfish abundance would therefore reduce the extent of their role in the ecosystem. It does not, as the quoted excerpt would appear to indicate, state that there would be negative impacts to the stream ecosystem from any disturbance of any type or intensity to crayfish abundance. No changes were necessary in response to this comment.

ENVIRONMENTAL IMPACTS OF COAL MINING			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		highly site-specific.	
OSM-2010-0021-0696	Murray Energy Corporation	OSMRE's method for determining affected streams is fraught with errors and uncertainties and lead to results that are not scientifically, technically, or statistically defensible.	The focus of the analysis is on evaluating how the Stream Protection Rule (and regulatory alternatives) will reduce adverse environmental impacts of coal mining, in particular on hydrology and water quality. Accordingly, the discussion in Section 7.3 of the RIA relates the rule elements to specific improvements in environmental metrics. These findings are summarized in Exhibit ES-4A, which describes each environmental improvement in terms of the rule elements triggering the benefit and the ecosystem services supported by the environmental improvement. More information relating the rule elements to particular environmental improvements is provided in Chapter 4 of the accompanying EIS.
OSM-2010-0021-0060	Ohio Department of Natural Resources	Chapter 4, Page 4-94, 2nd Paragraph "Finally, current regulations contain requirements for the construction of siltation and discharge structures to prevent additional contributions of suspended solids outside the permit area to the extent possible (30 CFR 816/817.46 and 816/817.47). These engineered features detain water, by design, until sediments have settled out to allow the effluent from the structure to meet state and federal effluent limitations. As a result, these structures alter the timing and amount of water that reaches streams, which in tum adversely impacts downstream habitats (U.S. EPA et al., 2003; Woody et al., 2010). The creation of artificial water bodies alters flow dynamics and flood regimes, promotes the biotic homogenization of in-channel environments, and can alter the influx of allochthonous organic materials that are essential to the energy flow and biological productivity in stream ecosystems (Jackson, 2005; Rohasliney and Jackson, 2009; Fritz et at., 2010; Palmer et al., 2010)." Comment: This statement appears to assume that such features are always permanent, which is not the case. Implying permanency to temporary features or actions, and then basing a rule on that implication, does not seem appropriate.	Thank you for the comment. While the alternatives, including the Preferred Alternative, do not assume that these features are permanent it is understandable that the text as written could be misconstrued as such. Edits have been made to the DEIS text. Additionally please see the discussion of "temporary" impacts contained in the preamble to the rule.

COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
OSM-2010-0021-0050	Wyoming Department of Environmental Quality: Air Quality Division	In consideration of the Affected Environment as well as Environmental Consequences for the Air Quality Resource, the DEIS fails to consider coal bed methane production wells. Coal bed methane production wells recover the methane for beneficial use in advance of mining rather than as a fugitive emissions source as characterized throughout the DEIS. The DEIS should be modified to address coal bed methane production wells and their beneficial nature.	The estimated emissions from surface and underground mines presented in Section 4.2.4 of the FEIS account for the fact that some mines capture methane generated from degasification systems thereby reducing emissions to the atmosphere. The methane emissions estimates presented are net of the methane that is recovered, as reported in the U.S. EPA's Greenhouse Gas Inventory reports. That is, the estimates of methane emissions from underground mines equal the methane liberated from ventilation and degasification systems, minus the methane recovered and used. The FEIS also notes that the objective of the U.S. EPA's Coalbed Methane Outreach Program is to promote the recovery and use of coal mine methane and that future voluntary involvement in this activity on the part of coal operations is uncertain. However, to the extent that participation grows over time, baseline (No Action Alternative) methane emissions associated with coal mining may decrease in the future.
OSM-2010-0021-0050	Wyoming Department of Environmental Quality: Air Quality Division	DEIS page 3-224, Figure 3.6-9 Nonattainment Areas in the Northern Rocky Mountain and Great Plains Region i. The URL reference for the figure is no longer valid. ii. OSM-2010-0021-0050	Wyoming Department of Environmental Quality: Air Quality Division	Wyoming Air Quality Standards and Regulation (WAQSR) Chapter 6, Section 2 covers general air quality permitting requirements for construction and modification of minor and major sources. A key cornerstone of WAQSR Chapter 6, Section 2 is the requirements for Best Available Control Technology for all sources. As a result, it is a mischaracterization to make such an overly broad statement such as that on page 3-225 "Therefore, dust emissions from mining activities caused by haul roads and conveyors are a concern in this region."	OSMRE appreciates the comment related to the statement in section 3.6.2.5 on dust emissions from mining activities. The text has been updated to state that per WASQR, Wyoming DEQ requires the use of Best Available Control Technology to minimize air quality impacts.

8. Public Health

PUBLIC HEALTH			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
OSM-2010-0021-0068	Earthjustice	OSMRE recently acknowledged the weighty scientific evidence that surface coal mining is causing disease and death in Appalachia. In light of that acknowledgment, there is no justification for OSMRE to fail to consider the public health consequences of its decision. Likewise, U.S. EPA's final action on the Spruce No. 1 Mine cited nine studies linking mountaintop removal mining and public health impacts.	OSMRE has considered the potential public health and safety implications of implementing Alternatives for the SPR, and discusses these in Section 4.3.4 of the EIS. Public health literature exists that link water and air quality to public health; these are benefits of the SPR. This section also states that in general, epidemiological studies are limited in their ability to prove a causal relationship, but continued positive findings obtained through a variety of study designs can provide a substantial weight of evidence in support of a causal relationship. The current body of evidence, while it does not reach that level, does suggest that further research on impacts of coal mining operations on nearby residents is warranted.
OSM-2010-0021-0068	Earthjustice	These health costs dwarf any economic Benefits to Appalachia from surface coal production. Using the value of a statistical life lost of $7.5 million, the deaths attributable to surface coal mining in Appalachia represent a total cost of $74.6 billion. "In contrast,…the direct (monetary value of mining industry jobs, including employees and proprietors), indirect (suppliers and others connected to the coal industry), and induced (ripple or multiplier effects throughout the economies) economic Benefits of coal mining to Appalachia…" are only $8.08 billion in 2005 US$.31	Thank you for your comment. Please refer to Master Response on Public Health Effects.
OSM-2010-0021-0039	Jim Thomas	The table on page 4-26 indicates major Benefits to public health. There is no data in the DEIS to backup this claim or any of the alternative analysis.	The evaluation of the potential impacts on public health is qualitative and relies primarily on the potential effects of the Action Alternatives on improving water quality. Impacts to water resources are anticipated associated with improving baseline monitoring, establishing evaluation thresholds to prevent damage, requiring mandatory evaluation of monitoring data, and improving techniques to better restore sites to premining conditions. Improvements in water quality may also benefit public drinking water suppliers by reducing pollutant levels and therefore costs of water treatment. The relative

PUBLIC HEALTH			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
			impact to public health and safety (e.g., minor, moderate, and major) is directly related on these impacts to water resources, which are dependent on the expected reduction in mining and extent of the geographic area impacted. Thus, areas that currently demonstrate the highest mining intensity are anticipated to experience the greatest impact to public health and safety. Please see Section 4.3.4.2 for additional details.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.0.3.7, p. 4-11 "Major Beneficial" impacts are anticipated as a result of several of the alternatives. These health and safety impacts are not defined and should be clarified along with their source for inclusion in the rule. Impacts to public health and safety are classified as major, moderate, and minor. However, there is insufficient information provided related to water and air quality to justify classifications. The discussion of baseline is focused on one watershed in Appalachia and provides no rationale or basis for classification of Benefits beyond this watershed or in other regions.	Public health impacts are explained in more detail in section 4.3.4 of the EIS, and rationale for impact determinations can be found in Table 4.3.4-4. Public health is an aspect of the human environment that is relevant to be analyzed under NEPA. The evaluation of the potential impacts on public health is qualitative and relies primarily on the potential effects of the Action Alternatives on improving water quality. Impacts to water resources are anticipated associated with improving baseline monitoring, establishing evaluation thresholds to prevent damage, requiring mandatory evaluation of monitoring data, and improving techniques to better restore sites to premining conditions. Improvements in water quality may also benefit public drinking water suppliers by reducing pollutant levels and therefore costs of water treatment. The relative impact to public health and safety (e.g., minor, moderate, and major) is directly related on these impacts to water resources, which are dependent on the expected reduction in mining and extent of the geographic area impacted. Thus, areas that currently demonstrate the highest mining intensity are anticipated to experience the greatest impact to public health and safety. Please see Section 4.3.4.2 for additional details.
OSM-2010-0021-0696	Murray Energy Corporation	OSMRE fails to evaluate the impact of unemployment on health care and the loss of medical Benefits. Adverse health impacts are in fact expected, as loss of employment may lead to loss of health insurance, especially in those communities that meet the environmental justice thresholds as outlined on page 4-326.	Section 4.3.1.1 of the EIS recognizes that where coal mining is a key employment opportunity, quality of life may be negatively affected by reductions in mining activity levels, depending on the level of alternative emerging industries and re-employment opportunities.

OSM-2010-0021-0696	Murray Energy Corporation	Section 4.3.4.1, pp. 4-288 to 4-291 The mere presence of a potentially toxic substance in water or fish tissue does not equate to a risk without a complete exposure route and a dose that is sufficient to elicit an adverse effect.	OSMRE agrees that the presence of selenium in water resources does not itself determine risk to aquatic life or to humans. U.S. EPA's 2016 "Recommended Aquatic Life Ambient Water Quality Standard for Selenium in Freshwater" reflect the latest scientific knowledge, and are expressed both in terms of fish tissue concentration (egg/ovary, whole body, muscle) and water concentration (lentic, lotic) (https://www.epa.gov/wqc/aquatic-life-criterion-selenium). These standards are designed to be protective of aquatic life. Section 4.3.4.1 has been updated to include information about U.S. EPA's 2016 aquatic life criteria for selenium, and to clarify where the text is referring to aquatic life versus drinking water criteria.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.3.4.1, p. 4-289, first paragraph The detection of selenium is implied to be a health risk. However, the mere detection of selenium in fish tissue is not associated with health risk (see U.S. EPA, 1989 for an understanding of the potential for health effects due to environmental exposures). The concentration of selenium in tissue AND consumption rate of this specific tissue together determine whether fish ingestion is a potential health concern. Selenium is almost always detected in marine and freshwater fish nationwide, and the diet is the primary source of this essential nutrient (ATSDR, 2003).	OSMRE agrees that the presence of selenium in water resources does not itself determine risk to aquatic life or to humans. U.S. EPA's 2016 "Recommended Aquatic Life Ambient Water Quality Standard for Selenium in Freshwater" reflects the latest scientific knowledge on this topic and recommends maximum selenium levels in terms of fish tissue concentration (egg/ovary, whole body, muscle) and water concentration (lentic, lotic) (https://www.epa.gov/wqc/aquatic-life-criterion-selenium). These standards are designed to be protective of aquatic life. Section 4.3.4.1 has been updated to include information regarding U.S. EPA's 2016 aquatic life criteria for selenium, and to clarify where the text is referring to aquatic life versus drinking water criteria.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.3.4.1, p. 4-289, last paragraph "There are additional studies that have found toxic levels of selenium in surface water near coal mining areas."The selenium concentrations listed in this section (maximum of 14.1 ppb) are below the federal maximum contaminant limit of 50 ppb for drinking water, which does not support the statement that "toxic levels of selenium in surface water" have been found near coal mining areas. Also, the additional studies referenced in this text all pertain to the	The value of 14.1 micrograms per liter is not a maximum, but an average. Based on U.S. EPA's 2016 aquatic life ambient water quality criteria for selenium, concentrations such as the 14.1 micrograms per liter cited in the text, have the potential to impair aquatic life while remaining within drinking water guidelines. While surface water concentrations in mountain top mining streams may remain within drinking water

		Mud River watershed only. OSMRE should provide examples for multiple watersheds given the complexity of geochemical influences on selenium nationwide.	guidelines as specified by U.S. EPA, the risk of bioaccumulation and biomagnification is the foodweb at these selenium concentrations represents an important potential pathway to human populations.
OSM-2010-0021-0696	Murray Energy Corporation	The relevance of stream selenium concentrations to public health is not clear. Unless the surface water concentrations shown in this figure represent drinking water concentrations, there is no direct link between selenium in the Upper Mud River and public health and safety, which is the subject of this DEIS section.	This section discusses the fate and transport of selenium in aquatic ecosystems. The information provided in this section discusses the flow of selenium from mine discharge to ambient water, which then can rapidly bioaccumulate in aquatic ecosystems and beyond. This text in this section has been clarified in that all referenced selenium criteria pertain to aquatic life rather than public health. Because humans are linked to aquatic ecosystems, selenium in aquatic ecosystems does represent a pathway for human exposure.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.3.4.1, p. 4-291, last paragraph "A study published in 2012 sampled the groundwater in 58 wells and springs in West Virginia. The study found elevated levels of selenium in general, and three of the samples tested exceeded U.S. EPA 's surface water quality criterion for selenium (5 ngL~) (Brantley, 2012)." Elevated levels of selenium in groundwater wells or surface water in coal-mining areas do not indicate there is a public health concern. Furthermore, exceedance of U.S. EPA's ambient water quality standard of 5 ppb is pertinent to an evaluation of ecological receptors, not public health. The U.S. EPA maximum contaminant level for drinking water is 50 ppb, a value considered protective of public health. This should be the standard used when assessing the potential for impacts to public health and should apply only to drinking water wells and other drinking water sources.	The text in 4.3.4.1 has been revised to clarify that Brantley, 2012 found selenium levels that exceeded the aquatic life ambient water quality criterion for selenium. However, Stout and Papillo (2004) identified selenium levels in at least one well that exceeded drinking water quality standards.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.3.4.1, p. 4-292, first paragraphOSMRE implies that selenium may be associated as the cause of polyps. The evidence, however, suggests that selenium accumulates as a result of the disease. Alimonti et al. (2008) noted that "the increment of Se [selenium] in cancerous patients has been tentatively viewed as an effort of the body to inhibit the growth of tumors."	The citation and excerpt provided by the commenter do not indicate definitive evidence that selenium accumulation increases only in defense against tumor growth.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.3.4.1, p. 4-292, second paragraph "Studies of populations in China living in an area with	OSMRE has noted in this paragraph that the dietary exposure levels in the studied Chinese

PUBLIC HEALTH			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		naturally occurring but unusually high environmental concentrations of selenium found that "chronic dietary exposure to excess levels of selenium has been associated with diseased nails and skin and hair loss, as well neurological problems, including unsteady gait and paralysis" (ATSDR, 2003, pg. 15)..." While exposure to high levels of selenium can result in adverse health effects, the discussion of dietary intakes by Chinese populations is not relevant to the typical intake levels in the U.S., which range from 0.071 to 0.152 mg/day (ATSDR, 2003). Based on the upper end of this range, the typical U.S. intake is almost six times lower than the effects threshold of 0.91 mg/day observed in the Chinese population (Yang, 1989). OSMRE should note that dietary intakes in China are not likely representative of intakes in the U.S.	populations may not be representative of U.S. populations. OSMRE appreciates the recommendation.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.3.4.1, p. 4-293, second paragraph The discussion of arsenic in drinking water found in coal-mining areas reported levels of 1 ppb (Central Appalachia) and 2.99 ppb (average for 13 counties in Kentucky). These levels are far below the current drinking water standard for arsenic set by U.S. EPA, which is 10 parts per billion (ppb) (U.S. EPA, 2001). This should be noted in the text. Comparing the concentration of arsenic to other carcinogens is not relevant given potential differences in carcinogenicity at different dose levels.	It has been noted in the text that these values are within U.S. EPA drinking water guidelines. However, NRC has indicated that lifetime risk of bladder and lung cancer from water arsenic exposure at three ppb is one in 1,000.
OSM-2010-0021-0696	Murray Energy Corporation	While elevated concentrations of sulfates may contribute to decreased pH in surface water and increased rates of diarrhea when present in drinking water, there is no discussion of sulfates from coal mining actually entering drinking water supplies… Detailed exposure information is unknown, and county of residence does not necessarily indicate exposure.	OSMRE agrees that there has been little study of the health effects associated with elevated sulfate concentrations in drinking water. The text does, however, discuss some of the known health effects associated with increased sulfate intake. While an understanding of direct impacts of sulfates on public health requires further study, elevated sulfate concentrations decrease pH and the increase in corrosiveness of stream water can potentially mobilize other contaminants with known adverse ecological effects.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.3.4.1, p. 4-293, Neither OSMRE nor any peer-reviewed study has established a causal link between the ecological integrity of streams and human cancer incidence. Temporality of exposure and disease cannot be assessed with this ecological study design. Detailed	Please refer to Master Response on Public Health. OSMRE acknowledges that more research is warranted to fully understand the causal relationships between mining related exposure and human health.

PUBLIC HEALTH

COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		exposure information is unknown, and county of residence does not necessarily indicate exposure. Controlling for occupational exposure is critical when assessing the potential for increased morbidity in exposed populations. The effects observed in women may also be due in part to occupational exposure of male coal miners due to the "take home exposure" effect whereby the worker brings contamination home with them at the end of the work shift (e.g., dust on clothes, boots, gear). Moreover, a number of flaws and limitations are present in these studies of cancer mortality in coal mining regions.	As stated in Section 4.3.4.1 of the FEIS, studies conducted to date attempt to control for other risk factors but more rigorous epidemiological studies are required to investigate these associations (e.g., long term prospective cohort follow up studies). In general, epidemiological studies are limited in their ability to prove a causal relationship, but continued positive findings obtained through a variety of study designs can provide a substantial weight of evidence in support of a causal relationship. The current body of evidence, while it does not reach that level, does suggest that further research on impacts of coal mining operations on nearby residents is warranted.
OSM-2010-0021-0696	Murray Energy Corporation	*Section 4.3.4.1, pp. 4-292 to 4-293* *Effects of Sulfates on Public Health* This two-paragraph section lacks clarity and organization. While elevated concentrations of sulfates may contribute to decreased pH in surface water and increased rates of diarrhea when present in drinking water, there is no discussion of sulfates from coal mining actually entering drinking water supplies.	The discussion of public health concerns related to sulfates has been revised in Section 4.3.4.1. to be more clear and to provide additional information.
OSM-2010-0021-0696	Murray Energy Corporation	*Section 4.3.4.1, p. 4-293, third paragraph* *It is possible that some areas may experience reductions in arsenic exposure in drinking water as coal production decreases.* There is no information in the text to support the assumption that arsenic in drinking water is related to coal mining. In fact, arsenic is a naturally occurring element that is found in drinking water throughout the U.S.	Section 4.3.4.1 states that while arsenic is naturally occurring, a major source of arsenic is pyrite, an iron-sulfide mineral, which is released into streams as part of acid mine drainage from coal mining. It is clear that drainage of iron-sulfide minerals into streams can be linked to surface coal mining. Studies such as Shiver (2005), which evaluated levels of arsenic across Central Appalachia, support this link.
OSM-2010-0021-0696	Murray Energy Corporation	*Section 4.3.4.1, p. 4-294, second paragraph 2012 retrospective cross-sectional study of county-level cancer mortality rate data from the Center for Disease Control (CDC) compared age-adjusted cancer mortality rates in Central Appalachian mountaintop mining counties versus Central Appalachian counties with other types of mining and counties with no mining. After controlling for covariates, the study found that lung cancer mortality*	Please refer to Master Response on Public Health. As stated in Section 4.3.4.1 of the FEIS, studies conducted to date attempt to control for other risk factors but more rigorous epidemiological studies are required to investigate these associations (e.g., long term prospective cohort follow up studies). In general, epidemiological studies are limited in their ability to prove a

PUBLIC HEALTH			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		rates were significantly associated with the presence of mountaintop mining in a community. The study also found evidence that mortality from leukemia, lung, bladder, and colorectal cancer were higher in mountaintop-mining areas compared to other mining areas, although the associations were not statistically significant. The magnitude of the association between mountaintop mining activity and cancer mortality was greater in more recent years (Ahern and Hendryx, 2012), reflecting the fact that some adverse health effects are not observed until years after exposure. Neither OSMRE nor any peer-reviewed study has established a causal link between cancer mortality and residence in coal mining areas. Temporality of exposure and disease cannot be assessed with this cross-sectional and ecological study design. Data measurements were at the county level, so group associations cannot be applied to individuals. Compared to the nonmining referent, mountaintop mining populations had higher smoking rates, higher poverty rates, lower college education levels, and higher adult obesity rates. Though analyses controlled for these covariates, residual confounding is possible. Other social, behavioral, and cultural variables not captured and adjusted for may have influenced results. Detailed environmental exposure information is unknown, and county of residence does not necessarily indicate exposure.	causal relationship, but continued positive findings obtained through a variety of study designs can provide a substantial weight of evidence in support of a causal relationship. The current body of evidence, while it does not reach that level, does suggest that further research on impacts of coal mining operations on nearby residents is warranted.
OSM-2010-0021-0696	Murray Energy Corporation	*Section 4.3.4.1, p. 4-294, second paragraph Other recent epidemiological studies have also found associations between adverse health effects (such as increased incidence of birth defects and increased adult mortality from cancer, heart, respiratory, and kidney disease) and residence in coal mining counties in Appalachia, after controlling for other risk factors (Ahern, et al, 2011; Esch and Hendryx, 2011; Hendryx, et al, 2010; Hendryx, 2009; Hendryx and Ahern, 2009; Hendryx and Ahern, 2008).* Neither OSMRE nor any peer-reviewed study has established a causal link between adverse health effects and residence in coal mining areas. In all studies referenced, temporality of exposure and disease cannot be assessed with this cross-sectional and ecological study	Please refer to Master Response on Public Health. As stated in Section 4.3.4.1 of the FEIS, studies conducted to date attempt to control for other risk factors but more rigorous epidemiological studies are required to investigate these associations (e.g., long term prospective cohort follow up studies). In general, epidemiological studies are limited in their ability to prove a causal relationship, but continued positive findings obtained through a variety of study designs can provide a substantial weight of evidence in support of a causal relationship. The current body of evidence, while it does not reach that level, does suggest that further research on

		design. Data measurements were at the county level, so group associations cannot be applied to individuals. Other social, behavioral, and cultural variables not captured and adjusted for may have influenced results. Detailed environmental exposure information is unknown, and county of residence does not necessarily indicate exposure. Data on smoking and drinking during pregnancy was self-reported and may have been underreported. Smoking and obesity rates were generally higher in mountaintop or other mining areas and may result in residual confounding. Though most analyses control for smoking, information on exposure to secondhand smoke was not collected. None of the studies control for occupational exposures.	impacts of coal mining operations on nearby residents is warranted.
OSM-2010-0021-0696	Murray Energy Corporation	Health outcomes experienced by both men and women do not imply that the cause is coal mining pollution. Other social, behavioral, and cultural variables could play a major role in increasing risk for the diseases investigated in these studies.	Please refer to Master Response on Public Health. As stated in Section 4.3.4.1 of the FEIS, studies conducted to date attempt to control for other risk factors but more rigorous epidemiological studies are required to investigate these associations (e.g., long term prospective cohort follow up studies). In general, epidemiological studies are limited in their ability to prove a causal relationship, but continued positive findings obtained through a variety of study designs can provide a substantial weight of evidence in support of a causal relationship. The current body of evidence, while it does not reach that level, does suggest that further research on impacts of coal mining operations on nearby residents is warranted.
OSM-2010-0021-0696	Murray Energy Corporation	*Section 4.3.4.1, p. 4-295, first paragraph* *In general, epidemiological studies are limited in their ability to prove a causal relationship, but continued positive findings obtained through a variety of study designs can provide a substantial weight of evidence in support of a causal relationship. The current body of evidence, while it does not reach that level, does suggest that further research on impacts of coal mining operations on nearby residents is warranted.* This section links incidences of cancer to surface mining but acknowledges that the current body of evidence does not prove a causal relationship. While some of this	As part of OSMRE's obligation under NEPA, the agency is required to consider all direct, indirect, and cumulative effects that may result from the regulation. Part of this body of effects includes health effects that may be associated with the rulemaking. Therefore, OSMRE believes that it is appropriate to incorporate epidemiological literature looking at coal mining associations with cancer risk to help evaluate potential direct or indirect effects that may result from the proposed rule.

PUBLIC HEALTH

COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		discussion may have some merit, it is misplaced in the DEIS as it is only weakly linked to the Proposed SPR through projections of increased or decreased coal mining.	
OSM-2010-0021-0696	Murray Energy Corporation	*Section 4.3.4.1, p. 4-297, third paragraph Swaen, et al. (1995) studied a sample of '3,790 coal miners that had abnormal chest x-ray films (suggesting pneumoconiosis) and found that deaths from gastric cancer were higher than expected, at 120 deaths. The fatality rate of pneumoconiotic coal miners due to gastric cancer resulted in a standardized mortality ratio of 147.5 (point estimate). Overall, their results suggest that pneumoconiotic coal miners have an approximately 22.5 percent to 76.3 percent higher gastric cancer fatality rate than the general population.* The study does not control for smoking. Smoking is a known cause of gastric cancer. Individual level exposure information was not available.	Please refer to Master Response on Public Health. While this particular study may not have controlled for smoking, the study cites several components of coal dust that underground coal miners are exposed to that may have carcinogenic effects. The other studies cited in section 4.3.4.1 attempt to control for many socioeconomic factors including smoking.
OSM-2010-0021-0696	Murray Energy Corporation	*Section 4.3.4.1, p. 4-297, last paragraph* *Hendryx and Ahern (2008) found that residential proximity to coal mining areas was associated with a higher risk for hypertension, kidney disease, chronic lung disease, and cardiopulmonary disease.* Neither OSMRE nor any peer-reviewed study has established a causal link between these health ailments and residence in coal mining areas. Temporality of exposure and disease cannot be assessed with this cross-sectional and ecological study design. Data measurements were at the county level, so group associations cannot be applied to individuals. Other social, behavioral, and cultural variables not captured and adjusted for may have influenced results. Detailed environmental exposure information is unknown, and county of residence does not necessarily indicate exposure.	Please refer to Master Response on Public Health. As stated in Section 4.3.4.1 of the FEIS, studies conducted to date attempt to control for other risk factors but more rigorous epidemiological studies are required to investigate these associations (e.g., long term prospective cohort follow up studies). 9. Compliance Costs

COMPLIANCE COSTS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
OSM-2010-0021-0068	Earthjustice	Absent such effective measures, OSMRE and the public will be left with mines that require expensive treatment of long-term discharges. Bonding systems are already under severe strain. While OSMRE correctly proposes to require permittees to post sufficient bonds to pay for that treatment, the forecasted long-term decline in coal production, combined with high industry debt loads, means that coal companies will lack the financial resources to post the large bonds that would be required to truly cover these treatment costs.	Chapters 4 and 8 of the RIA and Section 4.1.3 of the EIS report compliance costs of the rule alternatives. These sections have been revised in response to public comments in order to incorporate increased costs of bonding requirements. We note that the final rule language regarding bonding has also been modified in response to public comments.
OSM-2010-0021-0068	Earthjustice	Before it adopts a rule that relies on coal companies to finance the long-term treatment of pollution discharges, OSMRE must ensure that such treatment is not only technologically feasible, but economically feasible. Otherwise, after mining companies default on their obligations, the U.S. Treasury and taxpayer will end up paying for needed long-term treatment. OSMRE must therefore prepare a financial analysis showing that the coal industry is capable of carrying out the duties that OSMRE assumes it can handle, or adopt stricter protections that prevent these damaging activities in the first place	OSMRE has addressed these concerns in Section 800.9 of the final rule. Please see the discussion of bonding for long-term treatment of discharges in the final rule preamble.
OSM-2010-0021-0054	Kentucky Energy and Environment Cabinet	In addition, OSMRE did not analyze the effects of these changes in the DEIS or RIA. OSMRE mentions bonding in the DEIS in a brief two page section in Chapter 3, where they briefly describe the current state of bonding under SMCRA. OSMRE failed to analyze in any meaningful way the far-reaching effects the proposed changes to the bonding program would have on the various resources areas including the capability of the surety industry to support the increase in reclamation bonding. Furthermore, OSMRE fails to explain why such comprehensive changes to the bonding program were not analyzed in the DEIS.	Chapter 4 of the RIA and Chapter 4.1.3 of the EIS and RIA report compliance costs of the rule alternatives. These sections have been revised in response to public comments in order to incorporate increased costs of bonding requirements. We note that the final rule language regarding bonding has also been modified in response to public comments.
OSM-2010-0021-0049	Interstate Mining Compact Commission	Alternative 1 (No Action Alternative) (Effects of the Current Regulatory Environment (the No Action Alternative)- Regulatory Authority- Material Damage) p. 4-48 The National Pollutant Discharge Elimination System (NPDES) program prohibits water quality violations to occur within the permit boundary, and does not allow violations to extend outside the permit boundary. OSMRE fails to identify the need to place additional requirements on the applicant or	We identified all cost components associated with each part of the Rule using the amount of labor hours needed for additional requirements to achieve compliance by the applicant and the SRA. Please refer to Master Response on Industry Administrative Costs and Regulatory Authority Costs.

COMPLIANCE COSTS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		RA, and does not account for additional costs in making design showings and decisions.	
OSM-2010-0021-0049	Interstate Mining Compact Commission	Production costs for the Appalachian Region are already the highest of any of the coal producing regions and adding a disproportionate amount of the compliance costs resulting from the implementation of the proposed rule will place this region at an even greater disadvantage compared with other producing regions.	OSMRE acknowledges that the Appalachian Region has the highest cost of coal production under the No Action Alternative for the past several decades Appalachian coal mining has been at a disadvantage compared to mining in the western regions. The higher costs of production in Appalachia were considered in estimating the impacts of the increased costs of production that are anticipated due to the SPR, including potential implications on the cost-competiveness of surface versus underground production within and across coal regions.
OSM-2010-0021-0049	Interstate Mining Compact Commission	Any increased compliance costs will exacerbate the current regulatory expense incurred by a weakened coal industry. OSMRE provides examples of annualized compliance costs based on 2012 coal production levels and sales prices. OSMRE should use more current coal production levels in the context of each region, as the coal production landscape has changed significantly since 2012.	We agree that important changes have been occurring in the coal industry in recent years. The final FEIS reflects a revised coal market baseline to reflect these conditions, as well as two alternative baseline scenarios to reflect uncertainty.
OSM-2010-0021-0070	Luminant Mining Company LLC	The Proposed Rule imposes increased bonding requirements on certain types of bonds for stream restoration and restrictions. These changes to the bonding requirements will result in significant cost increases that are not adequately considered in the DEIS.	The FEIS and Final RIA have been revised to incorporate increased costs of bonding requirements. We note that the final rule language regarding bonding has also been modified in response to public comments.
OSM-2010-0021-0070	Luminant Mining Company LLC	These increased costs, which are not considered in detail in the Regulatory Impact Analysis or in the DEIS, will further add to the negative economic impacts of the Proposed Rule and must be fully considered. The adverse effects of the bonding requirements in the Proposed Rule are further discussed in Luminant's comments on the Proposed Rule.	The FEIS and Final RIA have been revised to incorporate increased costs of bonding requirements. We note that the final rule language regarding bonding has also been modified in response to public comments.
OSM-2010-0021-0696	Murray Energy Corporation	In addition, OSMRE did not analyze the effects of these changes in the DEIS. OSMRE mentions bonding in the DEIS in a brief two page section in Chapter 3, where OSMRE briefly describes the current state of bonding under SMCRA. OSMRE failed to in any way analyze the far reaching effects the proposed changes to the bonding program would have on the various resources areas. Furthermore, OSMRE fails to explain why such comprehensive changes to the bonding program were not analyzed in the DEIS.	The FEIS and Final RIA have been revised to incorporate increased costs of bonding requirements. We note that the final rule language regarding bonding has also been modified in response to public comments.

COMPLIANCE COSTS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
OSM-2010-0021-0696	Murray Energy Corporation	OSMRE must clarify whether the compliance costs apply to both surface and underground operations. The increased costs for the two types of mining should be separated and itemized individually given the differences in operations between the two.	OSMRE recognizes that surface and underground mining should be and are regulated separately. As such, estimates of increased compliance costs were developed separately for surface and underground mining throughout the RIA and EIS analyses.
OSM-2010-0021-0696	Murray Energy Corporation	Employment Impact Analysis Section 4.3.1.3, p. 4-187 This section states that the additional labor needed to perform the enhanced restoration required by the Proposed SPR would be beneficial to the communities and the region in which coal is mined. It does not, however, discuss the personnel that would be needed to conduct the environmental studies, the numbers of new environmentalists needed, or the possible costs associated with delay while waiting to hire or train these specialists.	The EIS in Chapter 4.3.1 recognizes that the Alternatives will result in costs to the industry as well as RAs that include monitoring and permitting-related requirements. The potential for increased employment requirements associated with these efforts is quantified.
OSM-2010-0021-0049	Interstate Mining Compact Commission	Model Mine Analysis- Total Compliance Costs Because most of the model mines have a higher production rate than the typical mines found in any given region, economy of scale suggests the cost per ton is underestimated for mines smaller than the model mines. Using this logic, the larger the mine, the cheaper it will be on a cost per ton basis to carry out extra monitoring and compliance duties. In applying these lower costs per ton to determine production impacts in each region, the DEIS underestimates the impacts to production and administrative costs to both RAs and industry. In addition, this method overstates the benefit of the action alternatives, including Alternative 8, and overstates the issues arising from the No Action Alternative. It underestimates costs to mining companies and budgetary requirements of RAs for the Action Alternatives. Therefore, the quantitative method developed in the Action Alternatives, including Alternative 8, is not based on real-world numbers.	The commenter is correct that for requirements that do not scale up and down with the amount of coal that is produced, the costs per ton for smaller mines of complying with the rule could be understated. However, the opposite would be true for mines that are larger than the model mines, i.e., costs could be overstated. For this reason, we believe that using a "typical" mine size is appropriate for calculation of the total industry costs as well as rule benefits. The potential impacts to small mines are discussed separately in Appendix A to the RIA.
OSM-2010-0021-0070	Luminant Mining Company LLC	We anticipate a similarly substantial increase in annual costs of reclamation due to additional environmental monitoring and site preparation costs, as well as more onerous standards for the essentially undefined goal of "restoration of the ecological function" of streams. These added compliance- and production-related costs will necessarily result in significant indirect impacts to employment and other socioeconomic factors.	OSMRE has clarified rule language to more clearly define restoring ecological function of streams; please refer to the Final SPR for updated text. Additionally, Chapter 4 of the RIA and Section 4.1.3 of the EIS report anticipated compliance costs of the rule.

COMPLIANCE COSTS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
OSM-2010-0021-0696	Murray Energy Corporation	Any increased compliance costs will exacerbate the current regulatory expense incurred by a weakened coal industry. The DEIS uses contextual examples for annualized compliance costs based on 2012 coal production levels and sales prices. The DEIS should use its own projected lower production and lower sales price to come up with the annualized compliance costs. Rough calculations indicate that the costs for Appalachian producers will be significantly higher (maybe 10%) than the example presented (between 0.06 and 0.24%).	The commenter is incorrect in that OSMRE used 2012 coal production levels and sales prices to estimate compliance costs. As described in EIS Section 4.1.3, compliance costs were determined by multiplying the estimated increased costs of coal production, per ton of coal production by the forecasted level of coal production over the study period (2020-2040). For additional details on these calculations of Coal production was forecasted over the study period for this analysis (2020-2040). Please refer to EIS Section 4.1.1.1 and 4.1.3 for additional detail.
OSM-2010-0021-0696	Murray Energy Corporation	Effects of Action Alternatives on Coal Production Section 4.1.4, p. 4-40 OSMRE has not provided a reasonable price forecast sufficient to permit evaluation and comment on this section. OSMRE predicts only the impact of the alternatives on the cost of compliance. In a period of rising prices, costs may be absorbed with little impact on profits; in a period of the falling prices, the inverse is true. There is no attempt at a sensitivity analysis in the prediction of costs, and ranges are not established. No estimate is factored into these predictions for delays and cost increases due to a shortage of compliance experts.	A sensitivity analysis was conducted on the major components driving compliance costs, including haulage costs, reforestation costs, production levels and stripping ratios. The results of this analysis are presented in Attachment A of RIA Appendix A. The Final RIA and EIS now also include quantified costs associated with delays related to bonding requirements in the SPR. Chapter 4 of the Final RIA describes the compliance cost estimation method in detail. Detailed assumptions about the administrative (paperwork and monitoring) requirements are presented as part of the PRA analysis in the preamble to the final rule.
OSM-2010-0021-0696	Murray Energy Corporation	Increased costs of compliance will cause companies to shutter marginal operations, thereby reducing nonproduction employees and vendor needs in even greater numbers than actual miners.	Thank you for your comment. We have evaluated the increased operational costs of the Alternatives and expect that costs to produce coal will reduce U.S. coal production by approximately 0.08 percent for the Proposed Action, which translates to less than two million tons per year on average. We estimate that employment associated with this reduction would be reduced, and agree that the marginal operators would be the most affected.
OSM-2010-0021-0049	Interstate Mining Compact Commission	In addition, OSMRE did not analyze the effects of these changes in the DEIS or RIA. OSMRE mentions bonding in the DEIS in a brief two page section in Chapter 3, where OSMRE briefly describes the current state of bonding under SMCRA. OSMRE failed to analyze in any meaningful way the far-	The FEIS and Final RIA have been revised to incorporate increased costs of bonding requirements. We note that the final rule language regarding bonding has also been modified in response to public comments.

COMPLIANCE COSTS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		reaching effects the proposed changes to the bonding program would have on the various resource areas. Furthermore, OSMRE fails to explain why such comprehensive changes to the bonding program were not analyzed in the DEIS.	
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.7.2, p. 3-232 "The area of study includes seven coal-producing regions containing lands where the federal government holds title to the coal, the surface estate, or both."OSMRE should note that all "federal lands," with some exceptions (for example, those set aside for Indian Tribes), are held in trust for the people of the U.S.; federal agencies are simply caretakers of those trust lands. As such, their job is to manage the resource for the benefit of the people, and as currently managed, governments gain significant revenues from mining royalties. These benefits will be lost if the regulation is finalized as proposed.	Mining royalties are based on 12.5% of the gross value of coal. About 98 percent of federal lands mined for coal resources are located in western states. The FEIS and RIA recognize that mining royalties would decline as coal production declines, all else being equal. As such, mining royalties would be expected to decline under the No Action Alternative, and would be reduced to varying degrees under the rule alternatives. The Preferred Alternative is anticipated to result in reductions of less than one million tons annually nationwide.

10. Industry Administrative Costs and Regulatory Authority Costs

INDUSTRY ADMINISTRATIVE COSTS AND REGULATORY AUTHORITY COSTS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
OSM-2010-0021-0066	NMA	Section 779.20 (d)(1)(ii) of the SPR states: "When the resource information obtained under paragraph (c) of this section does not include threatened or endangered species, designated critical habitat, or species proposed for listing as threatened or endangered, the Regulatory Authority must provide this information to the applicable regional or field office of the U.S. Fish and Wildlife Service only if the U.S. FWS requests an opportunity to review and comment on that information. The Regulatory Authority must provide the requested information to the U.S. FWS within 10 days of receipt of the request from the U.S. FWS." There is no economic analysis of the potential costs to the regulatory authority and/or permit applicants to provide fish and wildlife information or fish and wildlife protection and enhancement plans to the U.S. FWS, upon their request, for species that are not listed or proposed for listing under the ESA. This is an open-ended requirement that must be satisfied within 10 days of request which could potentially require a lot of staff time by the Regulatory Authority or permit applicant to meet the request within the allotted time frame. Additional protection and enhancement plans, if required by U.S. FWS, would increase costs to applicants to prepare as well as implement. The requirement to provide habitat enhancement, where practicable, is undefined. Requiring additional resource enhancement measures to meet an unknown measure of practicability could lead to extensive additional costs to the applicant both in the time it takes to get agreement with the U.S. FWS on acceptable enhancement measures, as well as the cost to implement them. There is no economic analysis of potential costs to the Regulatory Authority to facilitate this process, or to applicants who are required to be responsive to such requests from the U.S. FWS.	No additional analysis is required. SMCRA requires operations to minimize disturbances and adverse impacts of the operation on fish, wildlife, and related environmental values to the extent possible using the best technology currently available and to enhance those resources where practicable. 30 U.S.C. 1265(b)(24). As described in the DEIS description of the No Action Alternative, OSMRE's existing regulations already require minimization of impacts to fish and wildlife to the extent possible and enhancement where practicable. 30 CFR 816.97(a). Most of the alternatives would make habitat enhancement mandatory in certain situations (see Section 2.6 of the EIS). However, the commenter is mistaken in the assertion that U.S. FWS approval of the habitat enhancement plan is required. The RA may seek input on the requirements of the habitat enhancement plan from state and federal wildlife experts, but there is no obligation under existing regulations, or under the other alternatives considered within the EIS, for the RA to achieve agreement from U.S. FWS on the measures of the enhancement plan, unless it impacts a proposed or listed threatened or endangered species or proposed or designated critical habitat. Costs of implementation of enhancement measures were considered within the Regulatory Impact Analysis; As we note in the RIA, because compliance with permit conditions of the CWA and requirements related to ESA would require many of these same measures, the additional costs associated with habitat enhancement plan requirements under SMCRA were determined to be minimal.
OSM-2010-0021-0066	NMA	And, to have to provide the information within 10 days is unreasonable and burdensome to the Regulatory Authority	Current regulations at 30 CFR 780.16(c) already require the RA to provide the information

INDUSTRY ADMINISTRATIVE COSTS AND REGULATORY AUTHORITY COSTS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		(or applicant) in terms of additional time and monetary costs to provide the information in such a short period of time. The potential for an information request for a list of numerous species that are not listed or proposed for listing under the ESA is high. This is beyond the standard and regulatory process of ESA section 7, i.e., an assessment of impacts and a jeopardy determination for listed and proposed species. There is no regulatory reason for requiring the U.S. FWS or the applicant to provide information for species not listed or proposed under the ESA.	required under 780.16(a) to the Fish and Wildlife Service upon request, within 10 days of receipt of the request. The information required under paragraph 780.16(a) includes fish and wildlife resource information for all species, not just those species of plants or animals or their critical habitats listed by the Secretary under the Endangered Species Act of 1973, as amended (16 U.S.C. 1531 et seq.). Therefore the alternatives considered do not impose any additional time and monetary cost in comparison to the status quo. The authority for the existing requirement to gather information on fish and wildlife resources in general, and not just species that are listed or proposed, comes from section 515(b)(24) of SMCRA, which provides that, to the extent possible using the best technology currently available, surface coal mining and reclamation operations must be conducted to minimize disturbances and adverse impacts on fish, wildlife, and related environmental values and to achieve enhancement of those resources where practicable.
OSM-2010-0021-0049	Interstate Mining Compact Commission	OSMRE seems to greatly underestimate the cost to states to implement the Proposed Rule, especially in light of the fact that budget cuts in state agencies have been widespread in recent years. The proposed rule will require not only more manpower, but also experts in various scientific and technological areas that are currently not present or insufficient in many state agencies.	The estimated costs to regulatory authorities have been revised and additional supporting documentation has been added in the final RIA in response to public comments. Please refer to Master Response on Regulatory Authority costs.
OSM-2010-0021-0060	Ohio Department of Natural Resources	Abstract, 2nd Paragraph Comment: It is stated that the proposed rule is "intended to balance all relevant portions of the Act" including "ensuring a coal supply adequate for our Nation's needs." The rule itself does not appear to contain this balance. Impacts to coal production are understated in the DEIS based on actual numbers already evidenced in Ohio. Reductions in coal production have a direct impact to state permitting and	The commenter refers to historical changes in coal production in Ohio as a rationale for why the RIA and EIS estimates of impacts to coal production due to the SPR are underestimated. The historic changes in coal production in Ohio, as well as forecast future coal production without the SPR, are reflected in the baseline for the analysis, i.e., the No Action Alternative. The baseline forecast does not itself indicate

INDUSTRY ADMINISTRATIVE COSTS AND REGULATORY AUTHORITY COSTS

INDUSTRY ADMINISTRATIVE COSTS AND REGULATORY AUTHORITY COSTS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		regulatory staff numbers. Ohio has had to make staffing decisions and transfers to other sections within the Division of Mineral Resources Management to account for other federal regulations that have impacted coal production without implementation of the stream protection rule. Funding for state regulatory and permitting staff in Ohio and match dollars for grants from the OSMRE are projected to decrease to a level that a number of employees will need to be transferred to other sections or positions will be eliminated.	what additional costs and associated impacts that the SPR itself will have on coal production. The overall decrease in forecast coal production due to the SPR is anticipated to be modest, totaling a reduction of approximately 0.08 percent for the Proposed Action. While we recognize that this change may depress the need for RA staffing to some degree, permitting requirements are also anticipated to increase to some degree demand for RA resources under the SPR. Regulatory workload activity is dependent on the level of permits being administered and the number of new permit applications processed annually. These activities are in decline regardless of this Rule. It would be incorrect to say regulatory budgets and staff must increase from current levels as a result of SPR. The costs of the SPR to regulatory authorities have been revised in the final RIA and FEIS. Please refer to Master Response on Industry Administrative Costs and Regulatory Authority Costs.
OSM-2010-0021-0060	Ohio Department of Natural Resources	Comment: It is stated that the definition of material damage would also apply to the "indirect adverse impacts from subsidence and other adverse impacts (for example, dewatering of a stream caused by underground mining through a fracture zone)." Note that this statement does not distinguish between types of streams. Additional compliance workload for regulatory staff to assess damages and ensure that impacts to streams are rectified will be required if even indirect stream impacts result from mining.	The EIS and RIA recognize that the SPR may increase permitting requirements to some degree, which will increase demand for RA resources under the SPR. The estimated costs to regulatory authorities are estimated to increase by approximately $0.5 million annually across the U.S., representing approximately a 0.6 percent increase in RA expenditures. These estimates have been revised and additional supporting documentation has been added in the final RIA in response to public comments.
OSM-2010-0021-0696	Murray Energy Corporation	The laboratory analytical cost per sample (not including labor to collect the sample) under the No Action Alternative is ~$70; for seasonal sample collection (i.e., 4 seasons), the annual cost per stream location is $280. The per sample analytical cost under the Preferred Alternative is ~$255; for sampling 12 times per year per stream location the annual cost is $3,060. This represents a 1,100% increase in analytical costs per location. This does not include the	Costs associated with sampling were included in the analysis as presented in the RIA.

INDUSTRY ADMINISTRATIVE COSTS AND REGULATORY AUTHORITY COSTS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		additional labor and expense to collect samples at a much higher frequency (i.e., 12 times versus approximately 4), which would represent an even higher increase in sampling and analytical costs. (Standard Laboratory costs from TestAmerica, Inc.)	
OSM-2010-0021-0696	Murray Energy Corporation	In Chapter 4, there is no discussion of how the new regulations would affect the coal regulatory programs in different states. There is a large amount of variation in how state programs are run. Some have separate permit writers and inspectors; some do both permitting and compliance. There are other differences as well. These differences should be considered in the context of additional costs incurred by state regulatory programs.	The estimated costs to regulatory authorities have been revised and additional supporting documentation has been added in the final RIA in response to public comments. Specifically, section 4.4 and a section within section 4.5 of the RIA address regulatory expenditures in particular. Please refer to Master Response on Regulatory Authority costs for additional details.
OSM-2010-0021-0696	Murray Energy Corporation	Additional staffing will be required to implement the rule. OSMRE considers the additional employment by regulatory authorities as an offset to the loss of employment in the coal industry and the associated unemployment that goes with reduced coal production. This is not a realistic consideration of economic realities.	The analyses in the RIA and EIS do not assume that employment reductions that are estimated to result from decreased coal production will be offset by increases in government employment. Estimates of SPR implementation-related employment is associated only with industry employment. These jobs are linked to the amount of coal mined and the increased costs per ton, which varies by coal-producing region. We have adopted better terminology to help clarify this as a source of confusion in the Final RIA and EIS. Please refer to Master Response on Employment Effects and Multipliers and Regulatory Authority costs.

INDUSTRY ADMINISTRATIVE COSTS AND REGULATORY AUTHORITY COSTS

INDUSTRY ADMINISTRATIVE COSTS AND REGULATORY AUTHORITY COSTS			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
OSM-2010-0021-0696	Murray Energy Corporation	Section B.I, p. B-I From OSMRE's expectations for baseline inventory and monitoring of streams it is clear that substantially more technical compliance personnel will be needed by applicants, their consultants, and their respective regulatory authority. These individuals will need very detailed education and training. It is unlikely that this need can be fulfilled by reeducating laid-off miners.	The estimates of increased work requirements among various administrative activities required by the SPR were re-evaluated following public comment and, in some cases, increased. The estimated Industry Administrative costs were revised to reflect the level of effort corresponding to each part of the Rule in considerable detail. These costs increased on a per ton basis as a result of the revision. We recognized that regulatory authorities costs were not representative when expressed on a per ton basis. These costs are treated separately from industry cost in the revision. Please refer to Master Response on Industry Administrative Costs and Regulatory Authority costs.
OSM-2010-0021-0049	Interstate Mining Compact Commission	Alternative 2 (Groundwater) 2.4.2.1, p. 2-13 "... same frequency and for the same water quality parameters as surface ...." Monthly monitoring of groundwater is not generally necessary or a useful application of limited resources. Sampling on a too frequent interval typically results in redundant information that only adds costs to the applicant and does not add information that is valuable to the RA. Additional costs would be additionally incurred by the RA in storing and validation of the information. The DEIS and RIA do not consider those costs to RAs.	The alternatives (with the exception of the No Action Alternative and Alternative 9) within the DEIS proposed monthly baseline data collection for surface and groundwater for a 12-month period, followed by quarterly monitoring until final bond release. The frequency of baseline and monitoring is necessary to capture seasonal variability in water quality and quantity. These costs were accounted for in the DEIS and RIA. Please refer to Master Response on Industry Administrative Costs and Regulatory Authority Costs.

INDUSTRY ADMINISTRATIVE COSTS AND REGULATORY AUTHORITY COSTS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
OSM-2010-0021-0049	Interstate Mining Compact Commission	Increased Monitoring and Regulatory Program Staffing 4.2.1.2, p. 4-59 Footnote 14 "Peer reviewers noted that increased monitoring may not translate directly into better environmental protection if regulatory authorities are not sufficiently staffed to handle the added data review workload." State RAs largely do not have budgets to cover the costs of extra staff, so there is a good chance that increased monitoring would not provide better environmental protection. This statement is made in a footnote, and is contrary to the assertions contained in the DEIS. Furthermore, the RIA does not address the staffing needs and costs to RAs associated with increased monitoring.	Regulatory workload activity is dependent on the level of permits being administered and the number of new permit applications processed annually. These activities are in decline regardless of this Rule. It would be incorrect to say regulatory budgets and staff must increase from current levels as a result of SPR. In the revised RIA we explicitly show current regulatory costs for all State Regulatory Authorities (SRAs). Additional monitoring requirements would be largely carried out by the mine operators and not by the SRAs. The increase in administrative costs for SRA's from the Preferred Alternative would amount to $720 million or 0.6 % of current levels.
OSM-2010-0021-0060	Ohio Department of Natural Resources	Impacts to coal production and job losses are understated in both the DEIS and the RIA. The actual reduction in coal extracted will have a direct impact on state regulatory staff numbers. Funding for state regulatory staff in Ohio and match dollars for grants from the OSMRE will decrease to a level that a number of employees will need to be transferred to other sections or will lose their jobs entirely. As there needs to be funding to maintain positions, whether they are permit related and/or compliance related, the DEIS and RIA do not fully consider all the direct and indirect job losses associated with implementation of the stream protection rule.	OSMRE disagrees that implementation of the Proposed Action could result in budget shortfalls for state regulatory authorities. Although new requirements under the Proposed Action would increase the amount of work per new permit, the number of existing permits and the frequency of new applications is declining even without implementation of the Proposed Action. This trend is expected to continue independent of the Proposed Action, thereby reducing the overall workload for state regulatory authorities. Federal matching dollars for state regulatory programs would by law continue to be available to match state appropriations for the regulatory authority programs.

11. Employment Effects and Multipliers

EMPLOYMENT EFFECTS AND MULTIPLIERS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
OSM-2010-0021-0066	NMA	Further, it is uncertain, and unlikely that individuals displaced from coal sector employment will possess the necessary skills and experience to be competitive candidates for positions in health care and social service professions, without significant retraining. When calculating the “cost” of the SPR, at no point do either the DEIS or the RIA evaluate the cost (to the states or to the individual) of retraining, or the cost of lost wages during training periods, or the loss in lifetime earning potential if an individual is forced (at the period of time that should be his or her peak earning years) to take a lower paying position in a new industry.	The RIA recognizes that employment in the coal industry may be reduced in some areas due to the SPR. The RIA notes that additional work requirements of the SPR may include performing inspections, conducting biological assessments, and other tasks that require employment of highly trained professionals (e.g., engineers and biologists). Other increased work requirements associated with elements contained in the Final Rule are expected to require similar skills as currently utilized by the industry (e.g., bulldozer operations, haulage activities). The RIA quantifies the level of employment expected to be reduced within the industry and does not speak to how or whether particular individuals would seek job retraining. We note that Section 507(c) of SMCRA, 30 U.S.C. § 1257(c), establishes the small operator assistance program (SOAP). To the extent that funds are appropriated for that program, this provision of SMCRA authorizes OSMRE to provide small operators with training and financial assistance in preparing certain elements of permit applications. An operator is eligible to receive training and assistance if his or her probable total annual production at all locations will not exceed 300,000 tons.
OSM-2010-0021-0048	North American Coal	It’s also well-known that there have been significant changes in the energy industry, and more specifically the coal mining industry, over the past five years. These include changes in coal production and employment. For this reason we find that much of the data in Section 3.1.4 is significantly out-of-date, specifically data on poverty and unemployment, coal mining employment and payrolls (2011 data). The DEIS was published in mid-2015, so data should be made current through 2014, in order to be accurate and complete. Additionally, impacts based on these most recent data must also be brought up-to-date.	OSMRE agrees that important changes have been occurring in the coal industry in recent years. The final FEIS reflects a revised coal market baseline to reflect these conditions, as well as two alternative baseline scenarios to reflect uncertainty. Key aspects of section 3.14 have also been updated to be more current.
OSM-2010-0021-0059	CONSOL Energy	Section 4.3.1.2 of the DEIS states the following, "As developed in this chapter and as supported by economic	Please refer to Master Response on Employment Effects and Multipliers, which discusses the

EMPLOYMENT EFFECTS AND MULTIPLIERS			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		theory, environmental regulation can increase production costs, which according to economic theory should raise prices, reduce demand, and ultimately put downward pressure on employment within a given industry. However, compliance with environmental regulation also typically introduces additional labor requirements, which may mitigate that effect." This statement and the related paragraphs fail to take into consideration the full impact of the proposed SPR. The suggestion that environmental regulatory jobs could offset the lost coal mining and related jobs is simply not true. Also, without the mining industry many of the regulatory jobs would only be temporary.	detailed analysis of potential employment impacts. The analysis did not intend to imply that environmental regulatory jobs could offset the lost coal mining and related jobs. Section 4.3.1.2 has been clarified in response to public comments.
OSM-2010-0021-0061	Peabody Energy	Merely noting, for example, that Alternative 4 would result in an average of 310 lost coal production jobs (DEIS 4-360) in no way provides OSMRE (or the public) with any way of understanding the socioeconomic impact of 300 lost jobs.	As described in the RIA, job losses in the coal sector are anticipated to be less than one percent of coal sector employment. The analysis discusses the distribution of these impacts in the Environmental Justice section of the EIS.
OSM-2010-0021-0061	Peabody Energy	Footnote 4: As also touched on by NMA, OSM's suggestion that lost jobs in coal production will be offset by compliance jobs is irrational. Continuing with Alterative 4 as an example, after concluding that the alternative would result in an average of 310 lost production jobs, OSMRE concludes that an average of 370 compliance-related jobs will be created.	The RIA recognizes that employment in the coal industry may be reduced in some areas due to the SPR. The RIA notes that additional work requirements of the SPR may include performing inspections, conducting biological assessments, and other tasks that require employment of highly trained professionals (e.g., engineers and biologists). Other increased work requirements associated with elements contained in the Final Rule are expected to require similar skills as currently utilized by the industry (e.g., bulldozer operations, haulage activities). The RIA quantifies the level of employment expected to be reduced within the industry and does speak to how or whether particular individuals would seek job retraining. We note that Section 507(c) of SMCRA, 30 U.S.C. § 1257(c), establishes the small operator assistance program (SOAP). To the extent that funds are appropriated for that program, this provision of SMCRA authorizes OSMRE to provide small operators with training and financial assistance in preparing certain elements of permit applications. An operator is eligible to

			receive training and assistance if his or her probable total annual production at all locations will not exceed 300,000 tons.
OSM-2010-0021-0049	Interstate Mining Compact Commission	Cumulative Impacts -Job Loss 4.5.3.5, p. 4-360 Offsetting employment decreases in coal industry jobs with increases in compliance related employment is not economically feasible. A drastically reduced tax base resulting from reduced production will not support additional government employees. Increased costs of compliance will cause companies to idle or shut down marginal operations, thereby reducing non-production employees and vendor needs in even greater numbers than actual miners.	The RIA recognizes that employment in the coal industry may be reduced in some areas due to the SPR. The RIA notes that additional work requirements of the SPR may include performing inspections, conducting biological assessments, and other tasks that require employment of highly trained professionals (e.g., engineers and biologists). Other increased work requirements associated with elements contained in the Final Rule are expected to require similar skills as currently utilized by the industry (e.g., bulldozer operations, haulage activities). The RIA quantifies the level of employment expected to be reduced within the industry and does speak to how or whether particular individuals would seek job retraining. We note that Section 507(c) of SMCRA, 30 U.S.C. § 1257(c), establishes the small operator assistance program (SOAP). To the extent that funds are appropriated for that program, this provision of SMCRA authorizes OSMRE to provide small operators with training and financial assistance in preparing certain elements of permit applications. An operator is eligible to receive training and assistance if his or her probable total annual production at all locations will not exceed 300,000 tons.
OSM-2010-0021-0696	Murray Energy Corporation	Tables 4.3.1-5 - 4.3.1-12 (DEIS, at 4-193 - 4-207) of the DEIS show that for all of the Alternatives, the effect on production jobs will be negative for both surface and underground mining. However, OSMRE concludes that the magnitude of the effect will be negligible, with 260 FTEs lost in any given year, on average. This assertion has been more fully explored in other sections of this document with the conclusion that the overall job loss will actually be several orders of magnitude greater than predicted in the DEIS and RIA.	Please refer to Master Response on Alternative Analysis Provided by the National Mining Association, which discusses the differences in the assumptions made to conduct OSMRE's analysis and the National Mining Association's analysis. These different assumptions lead to different impact estimates, but as stated in the Master Response, Ramboll Environ's interpretation of the incremental changes in mining operations required to comply with the rule elements is inaccurate and extreme, which lead to erroneous estimates of the impacts on

EMPLOYMENT EFFECTS AND MULTIPLIERS			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
			coal production and employment. .
OSM-2010-0021-0696	Murray Energy Corporation	Chapter 3 of the DEIS provides the results of a detailed investigation into the distribution of jobs and wages across a number of sectors (including Health Care, Transportation and Warehousing, Construction, Retail Trade, and Professional Services). In Chapter 4, the authors of the DEIS suggest that increased labor demand in two sectors in particular (compliance and "other energy") will absorb lost coal sector opportunities (DEIS, at 4-184). This same claim that compliance and enforcement related jobs will increase is presented in the RIA (RIA, at ES- 25 and Chapter 4). When the regional data provided in the DEIS are examined closely it becomes unavoidably clear that these supposed job alternatives are not in fact the "saviors" that OSMRE would like them to be.	Please refer to Master Response on Employment Effects and Multipliers, which discusses the detailed analysis of potential employment impacts. The analysis did not intend to imply that these job alternatives would be "saviors" but to point out that potential increases in alternative industry employment may provide opportunities for individuals previously employed in the coal industry.
OSM-2010-0021-0066	NMA	First, the analysis grossly underestimates the overall magnitude of the impacts by suggesting that environmental compliance jobs would mitigate the loss of employment related to mining. Second, the analysis does not fully investigate the regional and local impacts of the SPR on employment, low income families, regional economies, municipal taxes, electricity supply, human health, and quality of life. The DEIS grossly under predicts or fails to fully consider the level of harm to the mining industry, public, and national economy that is likely to occur if the SPR is adopted as federal regulation.	Please refer to Master Response on Employment Effects and Multipliers, which discusses the detailed analysis of potential employment impacts as well as the potential for differences in impacts by region.
OSM-2010-0021-0066	NMA	The DEIS grossly under predicts or fails to fully consider the level of harm to the mining industry, public, and national economy that is likely to occur if the SPR is adopted as federal regulation. Second, the analysis does not fully investigate the regional and local impacts of the SPR on employment, low income families, regional economies, municipal taxes, electricity supply, human health, and quality of life.	Please refer to Master Response on Alternative Analysis Provided by the National Mining Association.
OSM-2010-0021-0066	NMA	The DEIS concludes that the magnitude of the effect will be negligible, ranging between 160 and 600 FTEs lost in any given year, on average, depending on the alternative. These job losses were based on unrealistic estimates of industry contraction and flawed input values to the EVA model (see	Please refer to Master Response on Alternative Analysis Provided by the National Mining Association.

EMPLOYMENT EFFECTS AND MULTIPLIERS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		Appendix E of the RIA). The conclusion that, in fact, the overall job loss is likely to be several orders of magnitude greater than the analyses in the DEIS and RIA suggest is presented above.	
OSM-2010-0021-0066	NMA	Compliance, enforcement and government sector employment are not evaluated at all in the DEIS and their contribution to overall employment and payroll are not explored in any way. This makes it difficult to confirm the DEIS claim in chapter 4 that this sector will be able to absorb those who are displaced from coal sector employment as a result of the SPR. It also makes it impossible to gage whether or not those “enforcement” positions will provide wages that are on par with those available in the coal sector.	This comment seems to imply that the EIS states or assumes that the SPR will result in a transfer of jobs from the coal industry to the government. This is not correct. As stated in Section 4.3.1 of the EIS, we anticipate that compliance with the SPR will require a range of skills that include coal industry efforts as well as those in other sectors, such as biologists. The detailed employment analysis is provided in this section as well as in Chapter 6 of the RIA.
OSM-2010-0021-0066	NMA	Other industry sectors will not be likely to absorb the unemployed miners. Using the data provided in Chapter 3 of the DEIS, a careful analysis of regional employment patterns (Chapter 3 pgs. 3-429-3-451) shows that for all regions, and for the Appalachian Basin and the Western Interior in particular, the dominant growth sector has been health care and social assistance. Yet the salaries associated with these new opportunities are, on average, 50% lower than salaries in the coal sector. For	The analysis does not describe sectors that would "absorb" coal sector job losses. Rather, the analysis reports in Chapter 6 of the Final RIA that some job losses may occur within the coal sector due to this rule. As described in Chapter 6 of the Final RIA, the analysis finds that much of the additional demand for compliance activities is most likely to be undertaken by mining companies at mining sites, e.g. additional haulage of coal.
OSM-2010-0021-0059	CONSOL Energy	The DEIS overlooks the full impact to regional and local economies, especially in Appalachia . In these regions, coal mining is often the primary source of jobs and revenue to local governments and school systems. Taking these remaining jobs away would devastate the local economies and lead to increased utility bills, depressed public and social programs and a lowering in the overall quality of life for people li vi ng in these communities. The DEIS underestimates these impacts and fails to fully consider the harm that may be caused by the proposed SPR at both the local and federal level.	Thank you for your comment. Section 4.3.1 of the EIS evaluates potential impacts of the SPR on employment, regional income, property value, tax revenues, and quality of life. T
OSM-2010-0021-0068	Earthjustice	OSMRE rejected the most protective alternative analyzed—alternative 2—in part due to predicted “Major Adverse impacts on socioeconomic conditions including, in particular, employment and severance taxes.” especially in Appalachia. DEIS at ES-39 to ES-40, 4-20. In doing so, OSMRE unlawfully and arbitrarily failed to consider the major economic costs that surface coal mining imposes on	Thank you for your comment. The purpose of the SPR is to reduce the impacts of coal mining on the environment. The impacts evaluated are related to incremental changes of the rule on the industry and the affected environment, rather than the overall social costs that may be associated with the operation of the coal

EMPLOYMENT EFFECTS AND MULTIPLIERS			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		Appalachia. Surface coal mining costs the economy of Appalachia more than it provides. Claims about the economic Benefits of coal mining—including OSMRE's—ignore the expenditures used to subsidize coal consumption and cover costs that are externalized by the industry. Significantly, the above studies do not account for the costs of illness and death that may be attributable to pollution from coal mining.	industry as a whole. As discussed in the analysis, the rule is anticipated to have a relatively small impact on overall coal production. The public health section of the FEIS (section 4.3.4) discusses the possibility that reduced coal production may result in improvements to public health.
OSM-2010-0021-0049	Interstate Mining Compact Commission	Most mining companies within the Appalachian Region have been operating at a loss for the past several years trying to stay solvent while hoping for an eventual change in market conditions and a return to profitability. The predicted production, job loss and compliance cost values presented in the DEIS are greatly understated and OSMRE does not provide any meaningful data to validate its conclusions.	Please refer to Master Response on Industry Operational Costs.
OSM-2010-0021-0070	Luminant Mining Company LLC	Conversely, as addressed more fully below, the Gulf Coast region will experience significant adverse socioeconomic impacts that promise to be far-reaching and extensive. A complete and lawful NEPA analysis would have required the agency to grapple with, and justify, the imbalance between these concededly limited, and questionable, Benefits, on the one hand, and the extensive costs to the Gulf Coast Region generally, and Texas specifically, on the other. Such an analysis would properly have led OSMRE to conclude that national application of a one size-fits-all rule is inappropriate.	The focus of the analysis is on evaluating how the Stream Protection Rule (and regulatory alternatives) will reduce adverse environmental impacts of coal mining, in particular on hydrology and water quality. Accordingly, the discussion in Section 7.3 of the RIA relates the rule elements to specific improvements in environmental metrics. These findings are summarized in Exhibit ES-4A of the RIA, which describes each environmental improvement in terms of the rule elements triggering the benefit and the ecosystem services supported by the environmental improvement. Additionally, as described in Chapter 3 of the RIA, the analysis evaluates the incremental effects of the rule, above and beyond any environmental improvements associated with existing regulatory requirements under SMCRA or the Clean Water Act. More information relating the rule elements to particular environmental improvements is provided in Chapter 4 of the FEIS. Finally, as described in Chapter 3 of the RIA, the analysis evaluates the incremental effects of the rule, above and beyond any environmental improvements associated with existing regulatory requirements under SMCRA or the Clean Water

EMPLOYMENT EFFECTS AND MULTIPLIERS			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
			Act. The Regulatory Impact Analysis carefully examined differences in costs across regions. In doing, so the analysis demonstrated that implementation cost on a per-ton basis would vary widely across coal mining regions. Such variation clearly demonstrates that the Rule is not a one size-fits-all rule.
OSM-2010-0021-0070	Luminant Mining Company LLC	Under NEPA, OSMRE must consider the Proposed Rule's indirect and cumulative effects. [...] CEQ regulations require that agencies consider these indirect effects. In the DEIS, however, OSMRE attempts to dodge this obligation with respect to employment impacts by stating that while "[t]he Action Alternatives (excluding Alternative 9) may generate indirect and induced effects . . . [,] these are not reported here because of the uncertainty associated with these calculations." The analysis of indirect effects is of critical importance in light of the Proposed Rule's potentially catastrophic impact on local communities. As the DEIS explains, "[i]ndirect effects arise from the 'ripple' effect of changes in coal production on local industries that provide goods and services to the coal industry."	Master Response on Employment Effects and Multipliers.
OSM-2010-0021-0070	Luminant Mining Company LLC	The DEIS concludes that the impacts of the Preferred Alternative on socioeconomic conditions in the Gulf Coast region will be "Minor Adverse or Negligible" when compared to the No Action Alternative, but provides no support whatsoever for this conclusion. This is a shocking underestimation of the impacts of the Proposed Rule, and lacks any rational basis in the analysis or data provided in the DEIS. OSM's "incomplete and misleading" analysis of socioeconomic impacts prevents decision makers and the public from accurately assessing the Proposed Rule. OSM's flawed analysis must be reconsidered with meaningful input from the coal industry and local governments, including the estimated impacts reflected in the Ramboll Environ study.	Please refer to Master Response on Alternative Analysis Provided by the National Mining Association.
OSM-2010-0021-0070	Luminant Mining Company LLC	The DEIS fails to adequately consider the fact that socioeconomic impacts will be felt most acutely on a local level, not on a regional or even state level. This is particularly true outside of Appalachia, where there is significant variation in the economic condition of local economies and employment prospects.	Thank you for your comment. Section 4.3.1 of the EIS evaluates potential impacts of the SPR on employment, regional income, property value, tax revenues, and quality of life. As noted, in areas that rely heavily on coal mining employment, reduced mining activity may affect the livelihood of the community. Individuals and families may rely on the

EMPLOYMENT EFFECTS AND MULTIPLIERS			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
			availability of mining jobs to provide income and benefits important to their well-being, such as health insurance. To the extent that impacts of the Proposed Action are concentrated in a particular community, these communities may experience a reduced quality of life to the extent that the Action Alternatives result in reduced mining activity.
OSM-2010-0021-0070	Luminant Mining Company LLC	The DEIS lists as cumulative actions several regulatory initiatives under the Clean Air Act that have a significant impact on coal mining under SMCRA and, more generally, the coal industry. These initiatives include the Mercury and Air Toxics Standards; the Cross-State Air Pollution Rule ("CSAPR"); the Clean Power Plan; and New Source Performance Standards ("NSPS") for EGU's. The potential impact of these initiatives cannot be overstated. Importantly, while U.S. EPA is exempt from the preparation of a NEPA document for these regulations promulgated under the Clean Air Act, OSMRE is not exempt from consideration of all direct, indirect, and cumulative impacts of actions as they relate to the Proposed Rule, which is issued under SMCRA. Because these past, present, and reasonably foreseeable actions, when viewed in light of the Proposed Rule, may have cumulatively significant adverse socioeconomic impacts on the same coal-mining communities and regions throughout the country, NEPA requires their analysis in the environmental document supporting the Proposed Rule. As such, the cumulative adverse socioeconomic impacts of these actions must be fully discussed in the EIS.	The Final RIA and FEIS for the SPR consider a number of recent U.S. EPA regulations as part of the baseline for the analysis. These are articulated in Chapter 3 and Appendix F of the RIA. These are also discussed in the cumulative impact analysis in section 4.5 of the FEIS. The Final RIA and FEIS baselines have been updated since the DEIS was released to the public.
OSM-2010-0021-0060	Ohio Department of Natural Resources	Chapter 4, Page 4-70, Streams, 4th Bullet "The length of downstream miles preserved varies across Action Alternatives primarily due to changes in coal production (see Section 4.1) expected as a result of the Action Alternatives (Table 4.2.1-12). The production changes generally influence between one and two percent of total affected downstream miles. The vast majority of preserved stream miles occur in Appalachia, the region anticipated to experience the greatest reduction in surface coal mining activity under the Action Alternatives." This indicates that the SPR will indeed negatively impact production levels, especially in the Appalachian Region.	Thank you for your comment. OSMRE agrees with this observation, as described in Section 4.1 of the EIS, the greatest forecast declines in coal production are expected to occur in the Appalachian Basin Region.

EMPLOYMENT EFFECTS AND MULTIPLIERS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
NA	EPA	We are pleased that the DEIS evaluates the impacts associated with the proposed alternatives on environmental justice communities. However, we note the lack of any identified coal-producing communities in West Virginia with low-income populations and the lack of discussion regarding disproportionate placement of adverse environmental, economic, social, or health impacts to low-income and minority populations from surface and underground coal mining activities. We recommend that this information be included in the FEIS. U.S. EPA would like to work with OSMRE on ways to clarify the environmental justice analysis.	According to the Council on Environmental Quality (CEQ) and U.S. EPA guidelines, a low-income population exists if the project area consists of 50 percent or more people living below the poverty threshold, as defined by the U.S. Census Bureau, or is meaningfully greater than the poverty percentage of the general population or other appropriate unit of geographic analysis. However, the term "meaningfully greater" is not defined. Public commenters and EPA suggested that the criteria to define "meaningfully greater" in the DEIS was too restrictive. As a result, the FEIS now considers any county with a population that has a poverty rate higher than the state average to be a low-income population. The FEIS finds that, of the 286 counties in the study area, 190 counties have populations that meet the specified low income and/or the minority population environmental justice thresholds. Of these 190 counties, 60 percent of them are in the Appalachian Basin. Of those counties in the Appalachian Basin, four have been identified as minority communities, 103 as low income communities, and nine as both low income and minority environmental justice communities.
OSM-2010-0021-0696	Murray Energy Corporation	OSMRE's analysis grossly underestimates job losses. Nonetheless, the loss of 15,000 out of 90,000 jobs (17% decline) (DEIS, at ES-46) is significant and supports the summary statement at ES-37 that this rule will have net negative economic effects.	This analysis did not identify 15,000 jobs as being potentially lost due to the SPR. The commenter is citing text that describes the expected decline in employment that is anticipated to occur in the coal industry even absent the SPR. The expected impacts of the SPR on employment are detailed in the socioeconomics impacts section of Chapter 4, and are anticipated to be much less.
OSM-2010-0021-0696	Murray Energy Corporation	OSMRE has failed to comply with its environmental justice obligations to consider the impact of its actions on socioeconomically depressed areas. Further, OSMRE's analysis on its face fails to clearly address other effects of the rule (e.g., increased energy prices and loss of jobs outside the coal industry). The loss of jobs in the coal	Section 4.3.1 of the EIS evaluates potential impacts of the SPR on employment, regional income, property value, tax revenues, and quality of life. As noted, in areas that rely heavily on coal mining employment, reduced mining activity may affect the livelihood of the

EMPLOYMENT EFFECTS AND MULTIPLIERS			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		industry does not happen in isolation; it precipitates loss of industry support jobs and loss of local community jobs when fewer people reside in a community or have the economic wherewithal to support a community.	community. Individuals and families may rely on the availability of mining jobs to provide income and benefits important to their well-being, such as health insurance. To the extent that impacts of the Proposed Action are concentrated in a particular community, these communities may experience a reduced quality of life to the extent that the Action Alternatives result in reduced mining activity. In addition, coal companies may have a philanthropic presence in communities; reduced mining could adversely affect these philanthropic activities.
OSM-2010-0021-0696	Murray Energy Corporation	Impacts of the Alternatives Section ES.8, p. ES-41 The Executive Summary suggests that there would be a reduced demand in coal production due, in part, to a reduction in demand from electrical generators and, in part, due to an increase in jobs associated with compliance. OSMRE acknowledges that this will lead to reduced employment in the mining sector and miner lay-offs. OSMRE fails to link job losses to reduced coal production and high coal operation costs that will drive some mining companies out of business	Estimated employment impacts for the U.S. coal industry are presented in Section 4.3 of the EIS. The distribution of these impacts (beyond the regional level) is impossible to predict. OSMRE's analysis cannot predict the distribution of employment impacts by mining company due to the large scope and scale of the Proposed Action. However the socioeconomic impacts of mining companies closing due to unfavorable economic conditions are captured by the regional analysis presented in the EIS.
OSM-2010-0021-0696	Murray Energy Corporation	OSMRE disingenuously (and without explanation) suggests that the loss of miner jobs could be offset by an increase in employment for regulatory compliance purposes. There is no evidence supporting the assumption that all miner training and education is transferrable to compliance-related work. Subsequent sections in the DEIS confirm that miners shifting to compliance work will need specialized education; however, the DEIS fails to acknowledge or address that compliance work will probably be in very short supply owing to the decline in the number of mining companies as a result of implementation of the Proposed SPR. The DEIS also fails to address delays in permit application preparations owing to a work force staffed by former mining workers with little practical experience working in the regulatory process.	The analysis does not intend to describe sectors that would "offset" or "absorb" coal sector job losses. The RIA recognizes that employment in the coal industry may be reduced in some areas due to the SPR. The RIA notes that additional work requirements of the SPR may include performing inspections, conducting biological assessments, and other tasks that require employment of highly trained professionals (e.g., engineers and biologists). Other increased work requirements associated with elements contained in the Final Rule are expected to require similar skills as currently utilized by the industry (e.g., bulldozer operations, haulage activities). The RIA quantifies the level of employment expected to be reduced within the industry and does not speak to how or whether particular individuals would seek job retraining. We note that Section 507(c) of SMCRA, 30 U.S.C.

EMPLOYMENT EFFECTS AND MULTIPLIERS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
			§ 1257(c), establishes the small operator assistance program (SOAP). To the extent that funds are appropriated for that program, this provision of SMCRA authorizes OSMRE to provide small operators with training and financial assistance in preparing certain elements of permit applications. An operator is eligible to receive training and assistance if his or her probable total annual production at all locations will not exceed 300,000 tons.
OSM-2010-0021-0696	Murray Energy Corporation	In the final section of ES.8, OSMRE acknowledges that the socioeconomic costs of the Preferred Alternative are a negative benefit, which should be considered in light of the overall coal industry shrinkage. The conclusion such costs would be "minor" was either determined before the recent decline in coal production and profits or is not based on accurate information. In all likelihood, the socioeconomic impact of the Proposed SPR will be major not minor.	Thank you for your comment. This comment does not provide support for your conclusion that impacts would be major. The OSMRE analysis is based on a detailed review of the estimated incremental impacts of the rule elements.
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.14.2, p. 3-409 Throughout this section, coal region conditions are compared, often unfavorably, with statewide data. However, due to the nature of the industry, coal mining counties are generally located in rural areas, and therefore a more analogous comparison would be with other rural communities. Therefore, OSMRE should compare coal communities with other similarly sized rural districts for a more appropriate analysis.	The analysis compares impacts to statewide statistics in an effort to provide a consistent measure across coal regions. For more details on specific counties please refer to the Environmental Justice analysis presented in Section 4.4 of the EIS.
OSM-2010-0021-0696	Murray Energy Corporation	Economic Conditions Section 3.14.2, p. 3-418 Table 3.14.6 -Coal Mining Employment and Annual Payroll By State 2011 There appear to be multiple errors and/or inconsistencies in this Table. For example, in the Gulf Coast region the Table lists 3,419 employees, a 424% growth rate in coal sector employment, a $199 million annual payroll with 12% annual payroll growth, and yet 0% contribution to total employment in the region. Similar errors appear with the Western Interior region. There is no explanation for these discrepancies. These errors call into question the accuracy of the entire table, which figures prominently in subsequent OSMRE calculations of impacts.	This table has been updated.
OSM-2010-0021-0696	Murray Energy	Tables 3.14-8a-3.14-8g- Coal Severance Tax Revenues in	Thank you for your comment. As severance

EMPLOYMENT EFFECTS AND MULTIPLIERS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
	Corporation	Coal Producing States 2012. These tables present severance tax revenues and their contribution to total sales tax revenues. While the percentage numbers themselves are small, even small contributions can have significant impacts in states, counties, and municipalities with tight and shrinking budgets. The DEIS does not make any effort to investigate (either in this Section, in Section 4.3—Social and Economic Resources—or in Section 4.4—Environmental Justice) the geographically specific impacts of changes to revenue or the multipliers of those changes.	taxes from the majority of the potentially affected states account for less than 0.2 percent of total state tax revenues, OSMRE does not anticipate that the predicted decline in severance taxes will have a significant impact on these communities. These impacts are evaluated at the state as well as the regional level. For example, Kentucky (1.62%), West Virginia (6.98%), and Wyoming (11.91%) are the only states in which severance taxes contribute more than 0.2 percent to total state tax revenues.
OSM-2010-0021-0696	Murray Energy Corporation	These tables depict negative trends in employment in the manufacturing, retail, finance, construction, wholesale, and administrative sectors, both in coal counties and at a statewide level in the Appalachian Basin. The tables show positive trends in health, professional services, management, and mining sector employment. A 2015 study completed by Ramboll Environ suggests that implementing the Proposed SPR will result in total coal-related job losses in the Appalachian region ranging between 30,115 and 52,556 direct jobs and between 79,142 and 190,415 including indirect and induced jobs along with direct. The growth sectors may in fact have to absorb many more positions than the DEIS predicts. In addition, the affected population is not likely to be qualified or mobile enough to take advantage of opportunities in growth sectors. The DEIS makes the assumption that they will be both qualified and mobile, but that is never demonstrated. If they are not, the DEIS does not address what measures might be taken to assist with a transition, and what those measures would cost. Therefore, the impacts of the Proposed Rule on EJ communities is underestimated.	Ramboll Environ's interpretation of the incremental changes in mining operations required to comply with the rule elements is inaccurate and extreme, which lead to erroneous estimates of the impacts on coal production and employment. As such, OSMRE disagrees with the commenter's statement that, "The growth sectors may in fact have to absorb many more positions than the DEIS predicts." In addition, while some work requirements of the SPR may include performing inspections, conducting biological assessments, and other tasks that require employment of highly trained professionals (e.g., engineers and biologists), other increased work requirements associated with elements contained in the Final Rule are expected to require similar skills as currently utilized by the industry (e.g., bulldozer operations, haulage activities). To the extent that individuals previously employed by the coal industry cannot find employment opportunities that meet their existing skill set, they may have to be trained and acquire skills in a new field. Please refer to the Master Response on Alternative Analysis Provided by the National Mining Association as well as the Master Response on Employment Effects and Multipliers for additional details.
OSM-2010-0021-0696	Murray Energy Corporation	The period of time stated for the EIS is misrepresented. Impacts to the mining industry will be incurred earlier than	As stated in the RIA and EIS, the onset of costs and Benefits of the Final Rule will depend, in

EMPLOYMENT EFFECTS AND MULTIPLIERS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		2020 because of the need for changes to practices, technologies, and other operations that require advanced investments and changes in practices, including financial practices. Hence, the EIS misses at least five years (from 2015) of economic, social, and industry impact	part, on the assumed timeline for implementation of the rule. Sixty days after OSMRE's final Stream Protection Rule is published in the Federal Register, it will take effect in states with Federal programs (currently Tennessee and Washington State, which have little coal production) and on Indian lands. Implementation in states with approved regulatory programs may take up to 42 months to develop regulations and policies consistent with this rulemaking. This equates to approximately 2020.
OSM-2010-0021-0696	Murray Energy Corporation	Mining secures some of the highest paying jobs available and creates, to some extent, usable flat land in the form of recontoured steep slopes in Appalachia. Utilities and infrastructure are a byproduct of a healthy economy, which a vibrant mining industry ensures (see comment on Section 4.0.3.6 below). The term "visual resources" is subjective. OSMRE did not state if or how the purported offense to Appalachia's residents due to the temporary sight of industrial activity was verified.	OSMRE agrees that visual resources are a subjective matter. Providing a broadly applicable mechanism to assess the value of manmade resources versus naturally occurring resources is outside of the scope of this effort. However, OSMRE has qualitatively evaluated the potential effects the alternatives would have on water quality, forest resources, and biological resources from proposed AOC and reforestation requirements. Better water quality and landscapes that are more representative of natural conditions for the site are environmentally preferable and improved aesthetics are assumed to also result. We do not disagree that the mentioned areas provide a valuable and aesthetically pleasing resource.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.0.3.6, p. 4-11 This is the first section that acknowledges the possibility of "Moderate Adverse" impacts to employment and income as a result of the Proposed SPR. It acknowledges "Major Adverse" impacts in Appalachia under Alternative 2. This section makes the assumption that a reduction of surface mining will lead to a balancing growth in underground mining and a concomitant substitution for employment. Indeed, because underground mining requires more hours of labor to produce a ton of coal than surface mining does, this shift may, the authors presume, cover all losses in surface mining. The section does not consider the reality that underground mining is also expected to contract under the Proposed SPR, and therefore will not be able to employ the newly	The potential increased costs of the SPR under Alternative 2 are anticipated to be large enough to alter the relative desirability of surface versus underground coal mining in Appalachia. This is not the same as assuming that this shift would "cover all losses in coal mining" as the commenter states. In fact, as described in the socioeconomic impacts section of Chapter 4, employment impacts would be significantly higher under Alternative 2 than under other alternatives.

EMPLOYMENT EFFECTS AND MULTIPLIERS			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		unemployed surface miners.	
OSM-2010-0021-0696	Murray Energy Corporation	Production costs for the Appalachian Region are already the highest of any of the coal-producing regions and further adding a disproportionate amount of the compliance costs resulting from the Proposed SPR implementation will place this region at an even greater disadvantage compared with other producing regions....Most mining companies within the Appalachian Region have been operating at a loss for the past several years trying to stay solvent while hoping for an eventual return to profitability. Enacting the Proposed SPR as proposed will further push more operators into bankruptcy, thus greatly reducing production and increasing job loss in the region. The predicted production and job loss values presented in the DEIS for the Appalachian Region are greatly understated.	OSMRE recognizes that conditions in the coal industry have been changing rapidly in recent years. In response to public comments, the baseline coal market forecast for the analysis has been updated. Please also refer to Master Response on Industry Compliance Costs and Employment Effects and Multipliers.
OSM-2010-0021-0696	Murray Energy Corporation	Social and Economic ResourcesSection 4.3, p. 4-182 - compared to Section 4.0.2.3, Table 4.0-1 (p 4-8) and Tables 4.0.2 to 4.0.17 (pp 4-13 to 4-28) The tables found in Section 4.0.2.3 indicate that the all of the alternatives will have some degree of negative economic impact across all regions and that the impacts will be most severe in the Appalachian Basin region. The definitions in the table found on page 4-8 delineate "major" and "minor" adverse effects based on recoverability, and the likelihood of recovery with or without support and intervention. However, the data presented in section 4.3 (as it relates to employment and economic opportunity) do not support the conclusion that impacts will be less than "Major Adverse" in any of the coal producing regions or for any of the affected environmental justice communities.	Each section in Chapter 4 includes a discussion of the effects of the current regulatory environment for that resource under the No Action Alternatives, the environmental consequences of the Proposed Action and alternatives on that resource, and, where adverse impacts of the action on the resource is anticipated, consideration of potential mitigation options for identified adverse effects. In response to public comment, we have added text to section 4.0 and individual resource sections in the FEIS that more clearly articulates the criteria for impacts used in this analysis. Please refer to specific chapter sections for details on these analyses.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.3.1.2, p. 4-184, first paragraph "Employment in the coal mining industry is expected to change as a result of several factors. The applicability of these factors varies by region, and some offset each other." OSMRE is incorrect that employment changes will offset each other. At a community level, where mine companies operate and interact with employees, employment losses will have significant impacts on local communities and county and state economies. Any potential job offsets will be inadequate.	The analysis does not intend to describe sectors that would "offset" or "absorb" coal sector job losses. The RIA recognizes that employment in the coal industry may be reduced in some areas due to the SPR. The RIA notes that additional work requirements of the SPR may include performing inspections, conducting biological assessments, and other tasks that require employment of highly trained professionals (e.g., engineers and biologists). Other increased work requirements associated with elements contained in the Final Rule are expected to

EMPLOYMENT EFFECTS AND MULTIPLIERS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
			require similar skills as currently utilized by the industry (e.g., bulldozer operations, haulage activities). The RIA quantifies the level of employment expected to be reduced within the industry and does not speak to how or whether particular individuals would seek job retraining. We note that Section 507(c) of SMCRA, 30 U.S.C. § 1257(c), establishes the small operator assistance program (SOAP). To the extent that funds are appropriated for that program, this provision of SMCRA authorizes OSMRE to provide small operators with training and financial assistance in preparing certain elements of permit applications. An operator is eligible to receive training and assistance if his or her probable total annual production at all locations will not exceed 300,000 tons.
OSM-2010-0021-0696	Murray Energy Corporation	OSMRE anticipates three possible responses to the overall decline in mining related employment: increased opportunity in underground mining; the ability to shift to jobs related to compliance and enforcement associated with the implementation of a new regulation; and a shift to jobs in another energy sector. OSMRE's analysis is flawed. The skills learned by the mining labor force have not been shown to be transferrable to most other employment sectors, with the exception of other mining sectors. A labor force migrating to compliance and enforcement is unrealistic given the projected declines in the mining sector that cause the job losses in the first place. Even if some of the labor force is transferable, a 2015 report by Ramboll Environ estimates employment loss from implementation of the Proposed Rule at between 112,757 and 280,809 total jobs throughout the economy (Ramboll Environ, 2015). An impact of this extent cannot be sufficiently balanced by the increased employment from compliance measures.	Ramboll Environ's interpretation of the incremental changes in mining operations required to comply with the rule elements is inaccurate and extreme, which lead to erroneous estimates of the impacts on coal production and employment. As such, OSMRE does not agree with the commenter's estimate of employment impacts of the SPR. In addition, while some work requirements of the SPR may include performing inspections, conducting biological assessments, and other tasks that require employment of highly trained professionals (e.g., engineers and biologists), other increased work requirements associated with elements contained in the Final Rule are expected to require similar skills as currently utilized by the industry (e.g., bulldozer operations, haulage activities). To the extent that individuals previously employed by the coal industry cannot find employment opportunities that meet their existing skill set, they may have to be trained and acquire skills in a new field. 			for additional details.
OSM-2010-0021-0696	Murray Energy Corporation	Action Alternatives and Potential Effects on Socioeconomic ConditionsSection 4.3.1.2, p. 4-184, second paragraphEmployment opportunities in alternate energy sectors are unlikely. OSMRE assumes several conditions will be met so that job losses may be offset: 1) The mine labor force is mobile; 2) Mining skills are transferrable to other job sectors; 3) Jobs in alternate energy sectors will appear instantly to capture labor lost by changes and shut down of mining operations; and 4) Income and Benefits between job sectors is lateral with no appreciable changes. OSMRE has not evaluated these and other factors, making OSMRE's assertions about offsetting job losses largely unsubstantiated.	The analysis does not intend to describe sectors that would "offset" or "absorb" coal sector job losses. The RIA recognizes that employment in the coal industry may be reduced in some areas due to the SPR. The RIA notes that additional work requirements of the SPR may include performing inspections, conducting biological assessments, and other tasks that require employment of highly trained professionals (e.g., engineers and biologists). Other increased work requirements associated with elements contained in the Final Rule are expected to require similar skills as currently utilized by the industry (e.g., bulldozer operations, haulage activities). The RIA quantifies the level of employment expected to be reduced within the industry and does not speak to how or whether particular individuals would seek job retraining. We note that Section 507(c) of SMCRA, 30 U.S.C. § 1257(c), establishes the small operator assistance program (SOAP). To the extent that funds are appropriated for that program, this provision of SMCRA authorizes OSMRE to provide small operators with training and financial assistance in preparing certain elements of permit applications. An operator is eligible to receive training and assistance if his or her probable total annual production at all locations will not exceed 300,000 tons.
OSM-2010-0021-0696	Murray Energy Corporation	OSMRE fails to demonstrate the substitutability of jobs across different employment sectors in states and regions where mining occurs. A labor force migrating to compliance and enforcement is unrealistic given the projected declines in the mining sector that cause the job losses in the first place.	The analysis does not intend to describe sectors that would "offset" or "absorb" coal sector job losses. The RIA recognizes that employment in the coal industry may be reduced in some areas due to the SPR. The RIA notes that additional work requirements of the SPR may include performing inspections, conducting biological assessments, and other tasks that require employment of highly trained professionals (e.g., engineers and biologists). Other increased work requirements associated with elements contained in the Final Rule are expected to

			require similar skills as currently utilized by the industry (e.g., bulldozer operations, haulage activities). The RIA quantifies the level of employment expected to be reduced within the industry and does not speak to how or whether particular individuals would seek job retraining. We note that Section 507(c) of SMCRA, 30 U.S.C. § 1257(c), establishes the small operator assistance program (SOAP). To the extent that funds are appropriated for that program, this provision of SMCRA authorizes OSMRE to provide small operators with training and financial assistance in preparing certain elements of permit applications. An operator is eligible to receive training and assistance if his or her probable total annual production at all locations will not exceed 300,000 tons.
OSM-2010-0021-0696	Murray Energy Corporation	U.S. home pricing data indicate that housing prices are significantly depressed in coal-producing counties. If unemployment leads to difficulties with missed mortgage payments and home foreclosures, the decrease in housing prices will have a devastating effect on communities, many of which already have higher poverty rates than the U.S. average (see DEIS, at 3-414 and 3-460).	Section 4.3.1 of the EIS evaluates potential impacts of the SPR on employment, regional income, property value, tax revenues, and quality of life. As noted, in areas that rely heavily on coal mining employment, reduced mining activity may affect the livelihood of the community. Individuals and families may rely on the availability of mining jobs to provide income and benefits important to their well-being, such as health insurance. To the extent that impacts of the Proposed Action are concentrated in a particular community, these communities may experience a reduced quality of life to the extent that the Action Alternatives result in reduced mining activity.
OSM-2010-0021-0696	Murray Energy Corporation	Employment Impact AnalysisSection 4.3.1.3, p. 4-191, last paragraph"Decreased coal production would lower demand for these goods and services provided, which, in turn, decreases income and employment in these supporting industries. As stated above, to the extent that coal production is replaced by extraction of another domestic fuel supply, employment impacts could be offset at the regional or national level by increasing employment in industries that extract substitute fuels, such as natural gas."The lower demand for goods and services will generate	The analysis does not intend to describe sectors that would "offset" or "absorb" coal sector job losses. The RIA recognizes that employment in the coal industry may be reduced in some areas due to the SPR. The RIA notes that additional work requirements of the SPR may include performing inspections, conducting biological assessments, and other tasks that require employment of highly trained professionals (e.g., engineers and biologists). Other increased

		job losses in other sectors because businesses will experience revenue losses stemming from higher local unemployment. The financial impact on communities that support mine operations will increase as a result of these so-called multiplier effects. With respect to employment opportunities in alternate energy sectors, OSMRE assumes several conditions will be met so that coal mining job losses may be offset: 1) The mine labor force is mobile; 2) Mining skills are transferable to other job sectors; 3) Jobs in alternate energy sectors will appear instantly to capture labor lost by changes and shut down of mining operations; and 4) Income and Benefits between job sectors is lateral with no appreciable changes. OSMRE has not evaluated these and other factors, making OSMRE's assertions about offsetting job losses largely unsubstantiated.	work requirements associated with elements contained in the Final Rule are expected to require similar skills as currently utilized by the industry (e.g., bulldozer operations, haulage activities). The RIA quantifies the level of employment expected to be reduced within the industry and does not speak to how or whether particular individuals would seek job retraining. We note that Section 507(c) of SMCRA, 30 U.S.C. § 1257(c), establishes the small operator assistance program (SOAP). To the extent that funds are appropriated for that program, this provision of SMCRA authorizes OSMRE to provide small operators with training and financial assistance in preparing certain elements of permit applications. An operator is eligible to receive training and assistance if his or her probable total annual production at all locations will not exceed 300,000 tons.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.3.1.4, p. 4-218, Table 4.3.1 -20 As with full-time equivalents, the Preferred Alternative results in an annual net negative impact on labor income on the order of $23 million dollars. Over a 20-year time horizon, that results in $460 million dollars in losses. Table 4.3.1-20 depicts negative effects for both surface and underground labor income, which reinforces the reality that underground mining opportunities will not be a substitute for surface mining work as suggested by OSMRE. Consequently, it is unclear how OSMRE can assert the economic consequences of the Proposed Rule and other action alternatives range from "negligible" to "minor adverse," depending on the region.	The anticipated annual decrease in production represents a very small percentage of the total U.S. coal industry. For comparison, total coal production was approximately one billion short tons in 2014. At an average cost of approximately $35 per short ton, total sales of coal from mines to the U.S. market was approximately $35 billion for that year.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.3.1.5, p. 4-220, footnote 40 "Statewide home values include urban and rural areas. Because coal mining largely occurs in rural areas, statewide home values may be an imperfect point of comparison, i.e., part of the differential attributed to coal mining may reflect a more general urban/rural disparity."As OSMRE recognizes here, statewide comparisons are inaccurate and misleading for coal mining, which occurs primarily in rural areas. OSMRE's socioeconomic analyses for mining regions should compare them with rural, perhaps agricultural, regions instead of	Statewide data on home values is the most detailed level of data available across the U.S. In order to maintain a consistent point of comparison across states and regions, these data were used as the best available option. As cited by the commenter, OSMRE notes in the EIS that the use of statewide data may be imperfect.

		comparing them with statewide values that including richer urban communities.	
OSM-2010-0021-0696	Murray Energy Corporation	In the summary associated with Table 4.2.3-2 (DEIS, at 4-139), OSMRE states: "To varying extents, all Action Alternatives (except Alternative 9) would decrease coal production. Under all Action Alternatives, coal production would decrease the most in the Appalachian Basin, Illinois Basin, and Northern Rocky Mountains and Great Plains regions." Studies have shown that when electricity/energy prices rise, middle and lower income households are impacted disproportionately: "eliminating coal . . . will increase the annual electricity bill for an average American family by up to $254. Furthermore, the shift away from coal places an unbalanced burden on the poor, raising their electricity bills by as much as 23 percent" (Maxwell, 2015).	Thank you for your comment.
OSM-2010-0021-0696	Murray Energy Corporation	Neither OSMRE nor any peer-reviewed study has established a causal link between proficiency rate in school and residence in coal mining areas. Temporality of exposure and disease cannot be assessed with this ecological study design...Detailed exposure information is unknown, and county of residence does not necessarily indicate exposure.	Thank you for your comment. Please refer to Master Response on Public Health for additional details on the existing research concerning public health impacts of coal mining.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.5.3.5, pp. 4-359 to 4-360 The "regulation-based" actions are overwhelmingly negative for socioeconomic effects. It is understandable that there is some price to pay for environmental stewardship, but the price is likely too high if it eliminates whole segments of a major industry.	Thank you for your comment.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.5.3.5, p. 4-359 "This analysis projects that coal industry employment will decrease by over 15,000 full-time equivalents (FTEs) under baseline conditions from 2020 to 2040."Coal mining employment's loss of an estimated 15,000 full-time equivalents does not factor in the 3 to 7 additional indirect jobs that depend on each direct mining job.	This analysis did not identify 15,000 jobs as being potentially lost due to the SPR. The commenter is citing text that describes the expected decline in employment that is anticipated to occur in the coal industry even absent the SPR. The expected impacts of the SPR on employment are detailed in the socioeconomics impacts section of Chapter 4, and are anticipated to be much less.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.5.3.5, pp. 4-359 to 4-360, bullets Claims of offsetting employment decreases in coal industry jobs with increases in compliance related employment (i.e., nonproduction overhead mining company employees, taxpayer funded government support personnel, various	The RIA recognizes that employment in the coal industry may be reduced in some areas due to the SPR. The RIA notes that additional work requirements of the SPR may include performing inspections, conducting biological assessments,

COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		additional vendor employees) demonstrate disregard for basic economics. A drastically reduced tax base resulting from drastically reduced production will not support additional government employees.	and other tasks that require employment of highly trained professionals (e.g., engineers and biologists). Other increased work requirements associated with elements contained in the Final Rule are expected to require similar skills as currently utilized by the industry (e.g., bulldozer operations, haulage activities). The RIA quantifies the level of employment expected to be reduced within the industry and does speak to how or whether particular individuals would re-enter the job market. The changes in employment that may occur due to the SPR are not characterized as offsetting each other. What is anticipated is that employment in the coal industry may be reduced in some areas due to the SPR. The RIA notes that additional work requirements of the SPR may include performing inspections, conducting biological assessments, and other tasks that require employment of highly trained professionals (e.g., engineers and biologists). Other increased work requirements associated with elements contained in the Final Rule are expected to require similar skills as currently utilized by the industry (e.g., bulldozer operations, haulage activities).
OSM-2010-0021-0068	Earthjustice	OSMRE states that it rejected more protective alternatives because their alleged negative impact on the nation's energy needs would be too great. 2015 DEIS at ES-36 ("OSMRE determined that the impacts to coal production from this Alternative were so substantial that they ran counter to the mandate under SMCRA 102(f) to balance the need for energy with the protection of the environment."). In making this determination, OSMRE failed to consider the fact that the nation's demand for coal is in sharp, sustained decline brought about by structural changes in the way energy markets are functioning. Reductions in coal production that would be associated with strong stream protections are a drop in the bucket compared to the large-scale, economy-wide transition away from coal that OSMRE admits is under way....In other words, market forces and other regulations are predicted to reduce	OSMRE has incorporated projected declines in U.S. and global demand for coal in its consideration between the alternatives as presented in the EIS and the RIA. As shown in Exhibit 5-8 of the RIA (Chapter 5), total coal production in the U.S. is expected to decrease over the 2020-2040 period under the Preferred Alternative, as it would by similar proportions under the other alternatives. The reduction in annual coal production is projected to be small ranging from 0.04 to 2.3 million tons per year. The reduction largely reflects power plant substitution of natural gas for coal due to increased coal prices. The increase in coal prices is driven by costs incurred by mines resulting from the proposed rule. However, the price of coal increase over the baseline price

		annual coal production by over 150 million tons per year. By contrast, the most environmentally protective alternative analyzed by OSMRE is projected to reduce annual coal production by only 3.2 million tons. DEIS at 4-42.	will not be exactly the same as the increase in the cost of compliance as markets adjust over time. The baseline demand for coal from a given region will be influenced by numerous exogenous factors (i.e., factors unrelated to this rulemaking), including: reserve depletion; changes in relative production costs; changes or limitations in transportation capability and cost; growing demands for low-sulfur coal; the abundance of, and relative cost of, alternatives to coal for electricity production (especially natural gas); changes in demand for steam coal resulting from the adoption of renewable portfolio standards for utilities; changes in demand for metallurgical coal (driven by domestic levels of iron and steel production, as well as demand from overseas); and changes in demand in the U.S. export market.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.6, p. 4-371, Table 4.6-7, "Socioeconomic Conditions" row Impacts to employment and income may be beneficial in some areas, where Benefits to employment from new compliance-related -work requirements more than offset production related employment impacts. OSMRE simplifies and understates one of the most serious consequences of the Proposed Rule. It is highly questionable whether the number of coal production jobs lost will be offset by compliance-related work in other job sectors (presumably consulting, permitting, monitoring, and environmental analysis work). Even if OSMRE's claims were true, the shift in jobs and employment are unlikely to benefit the same individuals who are currently employed in coal production. Skilled mine labor is not necessarily transferable or equivalent to skilled labor in the consulting, permitting, monitoring, and environmental analysis employment sectors. OSMRE appears to ignore the difficulty that operators will have in finding compliance specialists, many of whom will need university-level training, to complete the applications and monitor the operations. The loss of mining jobs will significantly affect the community and state economies. Moreover, the Proposed Rule will result in the loss of mines altogether, which, according to OSMRE's logic,	The RIA recognizes that employment in the coal industry may be reduced in some areas due to the SPR. The RIA notes that additional work requirements of the SPR may include performing inspections, conducting biological assessments, and other tasks that require employment of highly trained professionals (e.g., engineers and biologists). OSM-2010-0021-0696	Murray Energy Corporation	Section 3.14.2.5, p. 3-443"Table 3.14-13 Employment and Annual Payroll by Industry in the Northern Rocky Mountains and Great Plains"This table depicts positive growth for	Please refer to Master Response on Alternative Analysis Provided by the National Mining Association.

EMPLOYMENT EFFECTS AND MULTIPLIERS

COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		health, mining, transportation and warehousing, professional services administration, and food service sectors in the Northern Rocky Mountain region. The table depicts negative employment growth for construction, wholesale/retail trade and manufacturing sectors. The implication is that mining sector jobs that are lost as a result of the Proposed Rule will be offset by gains in these other sectors. However, the question left unanswered is whether the affected populations will be qualified enough or mobile enough to take advantage of sectors where opportunities exist. In addition, a 2015 analysis performed by Ramboll Environ suggests that the real impact of the Proposed SPR on coal jobs will be much greater than indicated by the DEIS, which suggests that the number of jobs that the growth sectors will need to absorb or create to offset coal sector losses may be greater than the DEIS predicts. This omission results in an underestimation of the impacts of the Proposed Rule on affected communities.	
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.14.2.7, p. 3-450 This table depicts negative employment growth in all sectors, except for health care, management, mining and professional services. As with other regions, the question here is, again, whether members of EJ communities, who will be disproportionately affected by the loss of employment opportunities in the coal sector, will be either qualified or mobile enough to take advantage of opportunities in growing sectors. In this region in particular, the economic impacts may be more significant because there are fewer sectors where growth is occurring. In addition, a 2015 analysis performed by Ramboll Environ suggests that the impact of the Proposed SPR on coal jobs will be much greater than depicted in the DEIS, which suggests that the number of jobs that must be absorbed or created in the growth sectors in order to offset coal sector losses is greater than this analysis suggests. This omission results in an underestimation of the impacts of the Proposed Rule on affected communities.	Please refer to Master Response on Alternative Analysis Provided by the National Mining Association.
OSM-2010-0021-0696	Murray Energy Corporation	OSMRE's cost calculations in the DEIS and RIA do not consider the costs (both to the states or to the individual) of retraining, lost wages during training periods, or the loss in lifetime earning potential if an individual is forced to take a lower paying position in a new industry (at the period of	The RIA recognizes that employment in the coal industry may be reduced in some areas due to the SPR. The RIA notes that additional work requirements of the SPR may include performing inspections, conducting biological assessments,

EMPLOYMENT EFFECTS AND MULTIPLIERS			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		time that should be his or her peak earning years). Lower salaries also translate to lower standards of living. Other sections of this analysis outline the impacts of decreased standards of living on health care and child welfare in particular.	and other tasks that require employment of highly trained professionals (e.g., engineers and biologists). Other increased work requirements associated with elements contained in the Final Rule are expected to require similar skills as currently utilized by the industry (e.g., bulldozer operations, haulage activities). The RIA quantifies the level of employment expected to be reduced within the industry and does speak to how or whether particular individuals would seek job retraining.
OSM-2010-0021-0696	Murray Energy Corporation	Home Ownership and Mobility There is an implicit assumption in the DEIS and RIA that not only will displaced coal sector employees be qualified to compete for positions in other sectors, but that they will also be able to easily migrate to areas within their states, or to other states, where employment opportunities may exist. For those families that own their homes, these homes often represent their largest single asset. This is no different for families from coal communities. Using publicly available census data, Ramboll Environ demonstrated that on average, coal producing counties have housing values that are 74% of the average home value in their State, and 56% of the average home value in the U.S. This varies by State, where coal counties in Wyoming tend to have similar home values to the U.S. as a whole, and coal counties in the Appalachian Region (Kentucky, Ohio, Pennsylvania, West Virginia) tend to have much lower housing values compared to both the U.S. average and the State average (Figure 1-4). This makes it unlikely that displaced coal industry employees could easily uproot and move to a different region of the country, since the value of their housing assets are disproportionately low. (U.S. Census Bureau, 2013). For example, in McDowell County, West Virginia, the average home value is $35,000, only 36% of the average State value of $98,500 and only 20% of the average U.S. home value of $176,700. These findings further suggest that relocation will not be as easy as the DEIS and RIA would suggest.	The analysis does not describe sectors that would "absorb" coal sector job losses. Rather, the analysis reports in Chapter 6 of the Final RIA that some job losses may occur within the coal sector due to this rule. As described in Chapter 6 of the Final RIA, the analysis finds that much of the additional demand for compliance activities is most likely to be undertaken by mining companies at mining sites, e.g. additional haulage of coal.
OSM-2010-0021-0696	Murray Energy Corporation	A comprehensive investigation of the full impact of a proposed regulatory change would examine all of these elements: direct, indirect, and induced effects, as well as backward and forward linkages. A thorough analysis would	Regional socioeconomic impacts are described in Chapter 6 of the RIA and in Chapter 4 of the EIS. For an explanation of why ripple effects were not included in this analysis, please refer

EMPLOYMENT EFFECTS AND MULTIPLIERS			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		look at these impacts not only on a national level, but at regional and local ones, as well. The DEIS and RIA do none of this. The presence of uncertainty when analyzing these impacts should not influence their inclusion in the RIA. Forecasting, by definition, includes uncertainty, and multipliers are designed to function while taking this uncertainty into account. There is no methodological rationale for choosing not to include ripple effects in the analysis.	to Master Response on Employment Effects and Multipliers.
OSM-2015-0002-0008	Natural Resource Partners LP	The Proposed Rule and accompanying analyses do not adequately address the economic impacts, including cumulative impacts of the federal government's rulemaking: Since 2011, more than 40,000 coal miners have lost their jobs. Recent reports state that for every one of those jobs lost, four more jobs are lost to the local economies.	Chapter 6 of the RIA discusses potential impacts of the proposed rule on employment in detail. The analysis focuses on presentation of direct regional economic impacts of the rule stemming from changes in coal production and compliance-related costs, but "ripple" impacts on the economy are also likely to occur associated with 1) changes in spending by local industries buying goods and services from other local industries (sometimes called indirect effects), as well as 2) changes in household consumption arising from changes in employment and associated income. We recognize the existence of these effects but do not quantify these in this analysis due to the high level of uncertainty associated with quantifying the scale of these effects. Section 4.5.3 of the EIS (Assessment of Cumulative Impacts) discusses the impacts of the proposed rule and its alternatives together with ongoing trends specifically as related to ongoing trends in coal industry employment. While the socioeconomic implications of the Action Alternatives are characterized as resulting in minor to moderate impacts, the cumulative impact of the Action Alternatives, in combination with other actions and trends, is classified as negative.
OSM-2010-0021-0039	Jim Thomas	The job loss numbers should include the cumulative impacts which are 3 indirect job losses per 1 direct job loss (Exhibits N and O).	Chapter 6 of the RIA discusses potential impacts of the proposed rule on employment in detail. The analysis focuses on presentation of direct regional economic impacts of the rule stemming from changes in coal production and

			compliance-related costs, but "ripple" impacts on the economy are also likely to occur associated with 1) changes in spending by local industries buying goods and services from other local industries (sometimes called indirect effects), as well as 2) changes in household consumption arising from changes in employment and associated income. We recognize the existence of these effects but do not quantify these in this analysis due to the high level of uncertainty associated with quantifying the scale of these effects.
OSM-2010-0021-0039	Jim Thomas	The cumulative effects analysis will lead you to believe the proposed rule would be positively beneficial to the industry. Further evaluation of cumulative impacts to public welfare and loss of jobs, wages, severance tax revenue, etc. must be assessed for each region that will be impacted. Significant impacts to human health would occur due to loss of income and therefore healthcare and the ability to maintain a self-supporting home-life. ... With already high poverty rates the cumulative effects on these areas would be significant.	An evaluation of the regional employment impacts associated with the SPR and its alternatives is presented in section 4.3.1.3 of the EIS (Employment Impact Analysis) as well as Chapter 6 of the RIA, which also includes a presentation of the impacts of the SPR on employment compensation. Section 4.5.3 of the EIS (Assessment of Cumulative Impacts) discusses the impacts of the proposed rule and its alternatives together with ongoing trends specifically as related to ongoing trends in coal industry employment. Section 4.3.1.6 of the EIS (Tax Revenue Impacts Analysis) evaluates the potential impacts of the SPR and its alternatives on severance taxes. Section 4.3.1.7 discusses potential impacts of the rule and its alternatives on quality of life. While the socioeconomic implications of the Action Alternatives are characterized as resulting in minor to moderate impacts, the cumulative impact of the Action Alternatives, in combination with other actions and trends, is classified as negative.
OSM-2015-0002-0077	NMA	One of the significant failures of the RIA and the DEIS is that neither provide a thorough investigation of the induced and indirect impacts of the Proposed Rule at the community level. The analyses present too general conclusions at the national level, and do not examine localized implications of the Proposed Rule.	In Chapter 4 of the RIA and Section 4.3.1 of the EIS. OSMRE recognizes that "ripple" impacts on the economy as a result of the SPR are likely to occur associated with 1) changes in spending by local industries buying goods and services from other local industries (sometimes called indirect effects), as well as 2) changes in household

EMPLOYMENT EFFECTS AND MULTIPLIERS			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
			consumption arising from changes in employment and associated income. OSMRE recognizes the existence of these effects but does not quantify them in this analysis due to the high level of uncertainty associated with quantifying the distribution and regional variation of these effects. Additionally, regional level impacts are provided throughout the RIA and DEIS for seven coal regions.
OSM-2010-0021-0056	Utah Mining Association	First, the analysis grossly underestimates the overall magnitude of the impacts by suggesting that environmental compliance jobs would mitigate the loss of employment related to mining. Second, the analysis does not fully investigate the regional and local impacts of the SPR on employment, low-income families, regional economies, municipal taxes, electricity supply, human health, and quality of life.	Please refer to Master Response on Alternative Analysis Provided by the National Mining Association.
OSM-2010-0021-0056	Utah Mining Association	The DEIS grossly under-predicts or fails to fully consider the level of harm to the mining industry, public, and national economy that is likely to occur if the SPR is adopted as federal regulation.	Please refer to Master Response on Technical Accuracy.
OSM-2010-0021-0056	Utah Mining Association	Many coal communities depend solely on this single resource industry for their economic survival. This dependence makes these communities particularly vulnerable to factors such as resource depletion, mine closures, shifts in world markets, or government policy changes. Dominated as they are by a single industry, these smaller communities cannot easily absorb the blows to their economy, tax base, and social structure when their main source of jobs and income shuts down.	Thank you for your comment. Section 3.14 of the EIS discusses the socioeconomic conditions in coal mining regions. Section 4.3.1 of the EIS evaluates potential impacts of the SPR on employment, regional income, property value, tax revenues, and quality of life. As noted, in areas that rely heavily on coal mining employment, reduced mining activity may affect the livelihood of the community. Individuals and families may rely on the availability of mining jobs to provide income and benefits important to their well-being, such as health insurance. To the extent that impacts of the Proposed Action are concentrated in a particular community, these communities may experience a reduced quality of life to the extent that the Action Alternatives result in reduced mining activity.
OSM-2010-0021-0070	Luminant Mining Company LLC	Other federal agencies have recognized the difference between lignite coal operations and other coal operations, not only because of the physical and other characteristics of	The baseline forecasts have been updated in the Final RIA to reflect the changing conditions in the coal industry.

COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		lignite, but also because of the prevalence of mine-mouth power plants that rely on a single source for fuel.51 This means that not only may lignite mining companies be required to shoulder enormous costs under the Proposed Rule, but also that power plants, utilities, and their customers may bear a disproportionate share of the burden. The DEIS does not take into account the different socioeconomic impacts for lignite coal mining and the Regulatory Impact Analysis did not differentiate between the impacts of the Proposed Rule on lignite mining as compared to other types of coal mining. As such, OSMRE should have considered as a reasonable alternative under NEPA an alternative that exempts lignite mining operations from the Proposed Rule.	
OSM-2010-0021-0070	Luminant Mining Company LLC	The DEIS concludes that the Proposed Rule will result in a loss of between only 41 and 590 full-time jobs each year, on average, under the Preferred Alternative. This estimate, however, was based on unrealistic estimates of industry contraction and flawed input values. OSMRE also assumes that job losses will be mitigated through compliance-related employment or other sector employment, but provides absolutely no basis for its assumptions. It appears that OSMRE relies for support of its estimates on the analysis in the Regulatory Impact Assessment that offsetting job increases created by the new compliance obligations combined with estimates of coal industry job contraction will result in insignificant employment impacts. However, estimates relating to job creation as a result of the rule are completely unsupported and speculative and have been called into question by Ramboll Environ's study.	Please refer to Master Response on Alternative Analysis Provided by the National Mining Association.

ENERGY MARKETS			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
OSM-2010-0021-0068	Earthjustice	Even without any action by OSMRE, OSMRE predicts "declines in surface coal production . . . in nearly all coal regions between 2020 and 2040, with annual production falling from 721 million tons to 610 million tons over the time period." DEIS 4-33. OSMRE predicts overall underground coal production to drop from 358 million tons to 306 million tons over the same period. Id. In other words, market forces and other regulations are predicted to reduce annual coal production by over 150 million tons per year. By contrast, the most environmentally protective alternative analyzed by OSMRE is projected to reduce annual coal production by only 3.2 million tons. DEIS at 4-42.	Thank you for your comment.
OSM-2010-0021-0068	Earthjustice	Clean air and climate policies, including the Clean Power Plan, will only accelerate this transition. "Nationwide, by 2030, [the Clean Power Plan] will achieve CO2 emission reductions from the utility power sector of approximately 32 percent from CO2 emission levels in 2005" and coal's share of generation capacity will drop from 39 percent today to "about 27 percent." Id. at 64,665. In other words, the U.S. electric power generation sectors' need for coal is projected to drop by about one third by 2030. Yet OSMRE predicts a decline in overall U.S. coal production of only "15 percent (162 million tons)." DEIS at 4-31. The upshot is clear: unless operators reduce coal production to a far greater degree than OSMRE forecasts, the current coal glut will only worsen as the supply of coal continues to drastically outpace declining demand from the power generation sector.	Thank you for your comment.
OSM-2010-0021-0696	Murray Energy Corporation	Limitations and Uncertainties Section 4.0.4, p. 4-29 This short section describes the shortcomings of OSMRE's analysis. In particular, both market conditions and mining costs are based on models. The mine cost models are to be found in the RIA. There is no discussion of recent shifts in energy markets such as the shift to low cost natural gas, nor is there a discussion of the potential uncertainty in both underground and surface coal production as a result of the Proposed Rule. This is	We agree that important changes have been occurring in the coal industry in recent years. The FEIS reflects additional text discussing a revised coal market baseline to reflect these conditions, as well as two alternative baseline scenarios to reflect uncertainty.

ENERGY MARKETS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		the greatest source of uncertainty and this should be evaluated in this section.	
OSM-2010-0021-0696	Murray Energy Corporation	However, inconsistently, OSMRE has chosen to use the 2014 analysis from Energy Ventures Analysis to define the forecasted coal production under the No Action Alternative as "a general decline in annual total surface and underground production of approximately 15 percent (162 million tons)." In contrast, EIA's Annual Energy Outlook 2014 with projections to 2040 shows an increase of 4.1% (44 million tons) over the study period (Table A15, Comparison of Total Production in years 2020 and 2040). As the evaluation of the No Action Alternative serves as the baseline against which all other alternatives are compared, this discrepancy is critical.	The energy market evaluation is detailed in Appendix F to the RIA, and represents a detailed year by year analysis of forecast coal demand under three baseline scenarios. A comparison of the baseline market forecast used in the RIA analysis with 2016 EIA reference and No Clean Power Plan coal demand forecasts is presented in the Executive Summary and Appendix F of the RIA. As shown, the low coal demand baseline scenario used in this analysis is similar, but somewhat lower, than EIA's current reference case (which assumes implementation of the Clean Power Plan), while EIA's "no Clean Power Plan" scenario forecasts baseline coal production that is similar, but somewhat higher, than the central case for this analysis. For additional comparisons to other existing coal forecasts, see an EIA review of coal forecasts, at http://www.eia.gov/forecasts/aeo/section_comparison.cfm. As shown, this comparison includes EVA forecasts in its comparatives.
OSM-2010-0021-0696	Murray Energy Corporation	*Section 4.3.2.7, p. 4-256, Illinois Basin Region Analysis indicates that this Alternative -would slightly decrease total coal production in this region, thereby slightly decreasing the total area of affected land use, reducing infrastructure demands, and lessening adverse impacts on visual resources and noise. Therefore, this Alternative -would likely have long term and small scope impacts and, thus, is classified as an overall Minor Beneficial effect on land use, utilities, infrastructure, visual resources, and noise.* A decrease in total coal production will undoubtedly create a negative impact for power utilities due to a loss of coal reserves for electricity production. OSMRE fails to adequately quantify the total area affected by the loss of coal reserves, which will be significant.	The rule provides analysis of the impacts of the SPR on utility prices. The volume of coal production anticipated to be reduced in quantified by region.
OSM-2010-0021-0068	Earthjustice	By failing to consider the dramatic declines in U.S. and global demand for coal, regulatory changes unrelated to the proposed rule that will only speed those declines, or the availability of ready alternatives (renewables, natural gas, and energy efficiency) to meet the nation's need for energy in the event that demand for coal did	The comment is incorrect. OSMRE has incorporated projected declines in U.S. and global demand for coal in its consideration between the alternatives as presented in the EIS and the RIA. As shown in Chapter 5 of the RIA, total coal production in the U.S. is expected to decrease over the 2020-2040 period under

ENERGY MARKETS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		somehow exceed supply, OSMRE has "entirely failed to consider an important aspect of the problem" when making its choice between regulatory alternatives. State Farm, 463 U.S. at 43. OSMRE has also arbitrarily relied on the nation's energy needs to reject stream protections that would not compromise the nation's ability to meet its energy needs.	the Preferred Alternative, as it would by similar proportions under the other alternatives. The reduction in annual coal production is projected to be small, ranging from 0.04 to 2.3 million tons per year. The reduction largely reflects power plant substitution of natural gas for coal due to increased coal prices. The increase in coal prices is driven by costs incurred by mines resulting from the proposed rule. However, the price of coal increase over the baseline price will not be exactly the same as the increase in the cost of compliance as markets adjust over time. The baseline demand for coal from a given region will be influenced by numerous exogenous factors (i.e., factors unrelated to this rulemaking), including: reserve depletion; changes in relative production costs; changes or limitations in transportation capability and cost; growing demands for low-sulfur coal; the abundance of, and relative cost of, alternatives to coal for electricity production (especially natural gas); changes in demand for steam coal resulting from the adoption of renewable portfolio standards for utilities; changes in demand for metallurgical coal (driven by domestic levels of iron and steel production, as well as demand from overseas); and changes in demand in the U.S. export market.
OSM-2010-0021-0696	Murray Energy Corporation	Industrial Use, Section 4.1.1.3, p. 4-34, Table 4.1-1Table 4.1-1 displays representative prices for coal in each region as dollars per ton. Coal is sold for its heat by dollars per million Btus. Prices per ton are secondary figures. Moreover, prices are shown as rising from today through 2040, which may not be accurate. The impact of the various regulatory alternatives on price thresholds needed to break even is not discussed.	The costs of the SPR are presented per ton of coal produced, and are then added to the costs of the price-setting mines in each region. The total costs are then converted to prices. In the coal market models, these prices are evaluated on a coal quality-adjusted basis (including heat content) to determine the dispatch of the respective coal plants.
OSM-2010-0021-0696	Murray Energy Corporation	Indirect Impacts Associated with Coal Combustion Section 4.2.4.7, p. 4-179 This section does not discuss the power requirements, kilowatt per ton of coal, for mining coal by underground methods, and therefore misses the total energy picture for underground mining.	The EIS focuses on understanding the incremental impacts of the rule on coal mining activities. The specific electricity requirements of underground mining are not anticipated to be directly affected by the rule.
OSM-2010-0021-0696	Murray Energy Corporation	Summary of Effects Section 4.3.1.8, p. 4-231 OSMRE's socioeconomic study does not consider how	The OSMRE study does consider electricity price impacts, as described in Section 4.3.2 of the FEIS. The impacts of the SPR on electricity prices are

ENERGY MARKETS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		electricity prices will increase and the impacts those increases will have. As electricity production becomes more expensive without coal, the price increase will be passed on to the consumer. Regions that depend heavily on coal for electricity will see higher increases in electricity prices than other regions. These regions will already be hard hit economically from coal employment losses. OSMRE fails to account for standard supply and demand market responses in this section.	determined by a dispatch model that considers the entire electricity market. Pricing in many regions is set by the marginal cost of production which in many regions is natural-gas fired combined cycle plants. As a result, the impact on electricity prices of the higher coal prices is muted.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.3.2.6, p. 4-254, first paragraph "If states that are heavily dependent on coal for electricity production lose supply due to the implementation of the Action Alternatives, costs per kilowatt hour may rise. Cost effects, however, would also be influenced by other market factors, such as the ability to substitute competitively priced alternative electricity generation sources and coal production changes amongst the regions." OSMRE is incorrect. The ability to substitute between energy sources depends on available existing excess capacity at nearby alternative source generating plants. Without excess capacity, new generating plants would need to be built, which takes capital and time investment. The extent will vary among regions.	The electricity model that is used to evaluate the SPR considers only available generating capacity which includes planned and expected capacity additions. EMILY
OSM-2010-0021-0696	Murray Energy Corporation	OSMRE over-simplifies the outcomes, which do not reflect regional impacts. It is difficult to import electricity from other regions, and long-term substitution ability takes capital, long-term investment, and significant time to convert, if there is no existing excess capacity. This creates a negative impact to the utility - in the short-term at a minimum.	The electricity model that is used to evaluate the SPR considers these regional factors in estimating the impacts of increased costs of coal production on utility pricing.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.3.2.7, p. 4-256, Appalachian Basin Region A decrease in total coal production in all of these regions as a direct result of the SPR implementation will undoubtedly create a negative impact for power utilities due to a loss of coal reserves for electricity production. OSMRE fails to quantify adequately the total areas affected in each region by the loss of coal reserves, which will be significant.	OSMRE's analysis did not conclude that a measureable loss of coal reserves is likely to occur due to the SPR. With respect to longwall mining, OSMRE found very few reserves that would be affected by the SPR. Given forecast demand, there was adequate longwall mining reserves for the forecast period. Please refer to Master Response on Alternative Analysis Provided by the National Mining Association.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.5.2.2, p. 4-335 "To the extent that these rules cause power producers to substitute natural gas and other alternatives for coal,	The sentence referenced by the commenter refers to the impacts of other federal regulations on energy markets. Our analysis includes assumptions about the

ENERGY MARKETS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		they will reduce future coal consumption and production from baseline levels." OSMRE fails to evaluate what will happen when the price of natural gas increases and supplies are not plentiful.	long term changes in the price of natural gas, and incorporates feedback impacts that could be associated with demand for coal production.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.3.2.6, p. 4-254, first paragraph OSMRE suggests that there is variability in the impact of changes in supply on cost per kilowatt hour—with some states experiencing cost reductions and others cost increases. However, the DEIS itself states, in the summary associated with Table 4.2.3-2 (DEIS, at 4-139): "To varying extents, all Action Alternatives (except Alternative 9) would decrease coal production. Under all Action Alternatives, coal production would decrease the most in the Appalachian Basin, Illinois Basin, and Northern Rocky Mountains and Great Plains regions." This suggests that in fact all regions will experience decreased supply and thus electricity costs will increase in all regions.	The effects of the Proposed Rule on cost per kilowatt hour may vary depending on a variety of factors, including individual states dependence on coal as an energy source and the ability to substitute alternative energy sources. However, in the context of the total coal supply and demand for utilities, the forecasted changes in production are expected to have a minimal measurable impact on utilities across the Action Alternatives. Language contradicting this conclusion has been removed.
OSM-2010-0021-0050	Wyoming Department of Environmental Quality	"The DEIS and DRIA appear to only utilize coal production and forecasts through 2012 to analyze impacts of the Proposed Rule. It is understood that there needs to be some practical cut of time for collecting and reviewing such date in order to develop environmental impact statements. While this may be the case, it is obvious that the recent changes and problems for the coal industry have been seismic. All evidence indicates that coal production has decreased dramatically in recent years and production is expected to continue to decline. This is a result of numerous factors such as the major increase in natural gas production and use, increased federal regulation and the world economic condition. (A recent study by the University of Wyoming projected a decrease in Wyoming coal production of 32% by 2025 (Godby et al., 2015, The Impact of the Coal Economy on Wyoming, http://www.uwyo.edu/cee/_files/docs/wia_coal_full-report.pdf). That number was published before the release of the final Clean Power Plan.) The coal production and growth models used as the basis for the DEIS are incorrect and not valid. They are so incorrect that the economic bases for the DEIS and the DRIA are seriously flawed.	While the commenter is correct that the RIA and EIS present some data that is summarized through 2012, the analysis utilizes a coal production forecast from 2020 through 2040 as the basis for the analysis. Further, OSMRE has revised the baseline coal production forecast since the draft analysis to reflect recent changes in coal market conditions.

COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
OSM-2010-0021-0056	Utah Mining Association	Coal generated electricity currently accounts for more than 70% of Utah's power consumption. The low cost energy coal provides is an important component of Utah's economic development strategy and is critical to Utah families and businesses.	Thank you for your comment.
OSM-2010-0021-0049	Interstate Mining Compact Commission	The agency has chosen to use the 2014 analysis from Energy Venture Analysis to define the forecasted coal production under the No Action Alternative as "a general decline in annual total surface and underground production of approximately 15 percent (162 million tons)". However, EIA's Annual Energy Outlook 2014 with projections to 2040 shows an increase of 4.1 percent (44 million tons) over the study period (Table AI5, Comparison of Total Production in years 2020 and 2040). As the evaluation of the No Action Alternative serves as the baseline against which all other alternatives are compared, this discrepancy is critical.	The baseline forecasts have been updated in the Final RIA to reflect the changing conditions in the coal industry. The RIA Executive Summary presents a comparison of our baseline forecasts to the most recent EIA forecasts.

MODEL MINES			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.1.6.2, p. 3-29 This section suggests the need for raw coal to be processed is related only to the presence of waste rock and sulfur. Processing is also necessary simply to meet customer sizing specifications. OSMRE should revise this section to reflect this additional reason for coal processing.	Thank you for the comment. Section 3.1.6.2 adequately addresses this topic to the level of detail needed for the EIS and no changes are required.
OSM-2010-0021-0049	Interstate Mining Compact Commission	Alternative 2 (Spoil replacement- mining through streams) 2.4.2.2, p. 2-16 "Placement of a layer of lower-permeability spoil or other material ..." If low permeability spoil is not available, it is unclear what "other material" would be. If it were imported material (clay), there would be a variety of cost, engineering and environmental implications, none of which is addressed by OSMRE.	The quoted text is in reference to the discussion of how an operator would meet requirements to restore flow to impacted surface waters once the strata in proximity to the surface water has been disturbed by mining. As part of the consideration of the feasibility of perched aquifer (aquitard) construction to achieve this purpose, OSMRE contracted an engineering firm to conduct an analysis of typical cost expectations for construction of aquitards to reestablish an intermittent reach in a typical surface mine identified in the model mine analysis. This analysis incorporated the cost of haulage of aquitard material, grading, compaction, haulage of free flowing fill and engineering of the design. Based on an assumption of a 5-acre perched aquifer size, the results were a calculated estimate of approximately $88 per foot for perched aquifer construction to return flow to a mined through intermittent stream. The engineering firm which conducted the analysis, Respec, ultimately provided several conclusions as a result: 1. Their professional opinion that a perched aquifer can be designed to store and feed water to a stream channel in a similar manner as the pre-mining groundwater system. However, they acknowledged that there are no known scientific studies to substantiate this opinion. They also stated that their knowledge, no coal mining company has ever constructed a

MODEL MINES			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
			perched aquifer to supply water to a restored stream. 2. Their opinion that flows measured at the toe of selected hollow fills monitored for an U.S. EPA water quality project in Kentucky indicate that an engineered perched aquifer has the potential to supply 2-4 GPM of flow per acre with similar rainfall as experienced in the Central Appalachia. 3. Their estimate that aggregate costs may amount to as much a 14% increase in overall restoration costs, but given that restoration costs are a relatively small component of the overall costs of implementation of the rule, the conclusion that this increase is not significant enough to change the financial modeling conducted at a per ton metric cost; it would contribute an additional $0.004 per ton of surface model mine reserves.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.1.3, p. 4-63 "[T]he method to quantify the reduction in stream miles filled and in ephemeral stream miles restored is a direct extrapolation from the model mine analysis described in Section 4.1. That is, the model mine analysis determines how mines in each coal region would implement the action alternatives, and how these practices would affect stream fill and stream restoration." The model mine analysis is not based on any kind of averaging or statistical analysis of real numbers. Instead, it is based on numbers that have been adjusted and inflated to poorly represent the mines with the highest production rates, rather than the majority of coal mines across the country. The arguments for all of the action alternatives are weak because of these biased and subjective bases.	The model mine analysis uses design elements from currently operating mines. Active mine permits with similar annual production tonnages to the regional representative tonnages were reviewed and used as a basis for designing the modelled mines. Please refer to Master Response on Model Mines Analysis for additional details.
OSM-2010-0021-0696	Murray Energy Corporation	OSMRE's analysis is generic, at best, and irrelevant to nearly every mine in every state where mining occurs. A "typical" (or grossly generic) mining operation is an unacceptable foundation for understanding the impact of a Proposed Rule that will have a substantially larger than	Given the scope of this analysis, OSMRE believes that the model mine analysis is an appropriate representation of the variety of mines and environmental conditions present in the mining industry. As stated in the Master Response on

MODEL MINES			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		$100 million dollar impact on the nation's economy. The use of statistical models involving probability distributions to capture the range of values associated with mine model parameters would be a necessary, obvious, and substantial improvement to the static modeling approach used by OSMRE in the DEIS. Another improvement to OSMRE's approach would be to evaluate representative mines in each mining region that reflect the range of environmental conditions likely encountered in the real world.	Model Mines Analysis, the model mine analysis uses design elements from currently operating mines. Active mine permits with similar annual production tonnages to the regional representative tonnages were reviewed and used as a basis for designing the modelled mines. Specifically, actual permits were used to define coal seam thicknesses, life of mine coal reserves, depth of cover and stripping ratios, stream impacts, mine impact acreage, reclamation plans, and other pertinent information related to each operation. The geographic location of each active permitted operation was also used to identify a realistic mining location for each model mine. The proximity of the model mines to the associated actual permits ensured the terrain and geology of the model mine operation mirrored the permits, while not asserting particular findings for particular already-operating mines.
OSM-2010-0021-0061	Peabody Energy	Response to whether the design event for a temporary diversion should be raised to the 25-year, 6-hour event to provide added safety and protection against overtopping. Response: We did not see data in the DEIS justifying an across the board raise to a 25yr, 6hr event. Increased cost both to industry and government should be accompanied by solid evidence of a widespread problem. The current design standards for temporary diversions have proven to be effective at all of our mine locations.	After considering all comments received OSMRE ultimately decided to retain the 10-year, 6-hour design criteria because it provides sufficient protection. The 25-year, 6-hour criteria provides minimal risk reduction at the price of significant additional cost and land disturbance.
OSM-2010-0021-0071	Resource Development Council	The DEIS seems to assume that only proposed mines that will result in permanent adverse impacts will not be permitted. The SPR appears to preclude the permitting of mines even where there are temporary impacts. Such discrepancies result in the agency potentially underestimating impacts in the DEIS that do not reflect the actual text of the SPR.	As proposed the SPR definition of material damage to the hydrologic balance outside the permit area did not differentiate between permanent or long-term impacts and temporary or short-term impacts. However the impact (temporary or permanent) would only be considered to be material damage if it was severe enough to preclude a designated, existing, or reasonably foreseeable use of surface water outside the permit area, or an existing or reasonably foreseeable use of groundwater outside the permit area. As proposed under the SPR Isolated noncompliant discharges would not be considered material damage unless those discharges were of a magnitude sufficient to preclude a protected use.

MODEL MINES			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
			The DEIS did not present this specific clarification within the discussion of alternatives that proposed a national definition for material damage to the hydrologic balance outside the permit area (i.e. the Proposed Action and alternatives 2, 3 and 4). However the DEIS analysis was conducted under the same assumption; permits could and would be authorized for operations that had temporary impacts so long as those impacts did not reach the level of MDHB under the definition (or lack thereof) being analyzed under that alternative.
OSM-2010-0021-0047	Society for Mining, Metallurgy & Exploration	For purposes of assessing environmental impacts, surface disturbance in acres per year would be a more appropriate measure than production rate. Basing potential environmental and economic impacts on production rates does not adequately consider environmental and economic conditions. The model mines have a higher production rate than the majority of mines in a given coal region. This higher production rate underestimates the cost per ton the rule may have on mines that produce less than the model mine. We are concerned that using the overestimated production rates in the model mine analysis provides an inadequate and inappropriate basis for the environmental and economic analysis included in the Draft Environmental Impact Statement. We believe it is not appropriate for OSMRE to base the model mine solely on production if the intent of the model mine is to assist with assessing environmental and economic impacts.	Differences in acres of surface disturbance by region were included in the development of representative model mines for each region. For more details on the variables considered in the development of the model mines, please refer to Master Response on Model Mines Analysis.
OSM-2010-0021-0049	Interstate Mining Compact Commission	Effects on Water Resources Table 4.2.1-1, p. 4-55 Primary Effects on Water Resources in Comparison to the No Action Alternative column The majority of the rule elements outlined in the table do not appear to result in improved stream water and groundwater quality or preserve streamflow and ground water quality. While some elements of alternatives could directly affect water resources under certain circumstances, the question of whether or not some of the alternative elements affect water resources in comparison to the No Action Alternative depends on site-specific conditions. No site-specific conditions are considered in	The next column in the referenced table provides an explanation for the primary effect claimed on water resources. These explanations provide support for the finding that water resources will benefit as a result of the rule elements. In addition, a variety of site specific information was included in the development of the model mines. Please refer to Master Response on Model Mines Analysis for additional information on what variables were considered in this analysis.

MODEL MINES			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		the DEIS, instead OSMRE relied upon a flawed model mine approach to determine resource impacts.	
OSM-2010-0021-0049	Interstate Mining Compact Commission	Defining Material Damage 4.2.1.1' p. 4-48 "SMCRA regulatory authorities have historically relied upon a qualitative approach whendefining material damage to the hydrologic balance outside the permit area and have notspecifically assigned numerical values to the point at which material damage to the hydrologic balance outside the permit area would occur."For Alternative 8, a quantitative method for determining material damage to the hydrologicbalance is presented. However, this method is not based on an objective scientific approach. Itis based primarily on the model mines approach, which is fundamentally flawed as explained throughout this document. The model mines were developed using subjective, qualitativereasoning. The production rates are overestimated, but are used in methods for calculatingmaterial damage to the hydrologic balance. This approach does not yield a valid numericalresult.	The commenter is incorrect in his statement that a quantitative method for determining material damage to the hydrologic balance is presented for Alternative 8. The commenter is also incorrect is his statement that the model mines were developed using subjective and qualitative reasoning. As stated in the Master Response on Model Mines Analysis, a variety of site specific characteristics were considered in the development of the model mines that are based on data from actual mines. Please refer to the Master Response on Model Mines Analysis for additional details.
OSM-2010-0021-0049	Interstate Mining Compact Commission	The model mine analysis is at best difficult to understand and is not adequately documented. This is particularly important because much of the subsequent analysis and conclusions of the DEIS are based on the model mine approach. The lack of information associated with the model mine approach leaves one wondering how OSMRE was able to analyze environmental and economic impacts associated with the proposed rule. The lack of fundamental site-specific data and inability to validate this model make its use problematic. Models must be calibrated to real-world conditions and validated by comparing model predictions to actual site conditions. This model has not been calibrated or validated, and, as such, does not meet the best available science criteria that NEPA demands.	As stated in the Master Response on Model Mines Analysis, a variety of site specific characteristics were considered in the development of the model mines. Please refer to the Master Response on Model Mines Analysis for additional details. Additional documentation on the model mine analysis is presented in Appendix B of the RIA. The model mine analysis was also peer reviewed by experts in the mining field.
OSM-2010-0021-0049	Interstate Mining Compact Commission	Model Mines - Limitations and Uncertainties4.0.4, p.-29"To capture the heterogeneity of the coal industry, the analysis employs 13 model mines across the U.S. This approach strives to capture the overall scope and scale of potential changes under each Alternative, but is not likely to be accurate for any specific mining operation."The model mines created for this analysis cannot be calibrated to or validated by actual mine operations, therefore it is	As stated in the Master Response on Model Mines Analysis, a variety of site specific characteristics were considered in the development of the model mines, using design elements from currently operating mines. Please refer to the Master Response on Model Mines Analysis for additional details on the development of the model mines.

MODEL MINES			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		of questionable value. With OSMRE' s access to real world mine permits and associated data, it is uncertain why OSMRE chose to "create" mines for purposes of this analysis.	
OSM-2010-0021-0049	Interstate Mining Compact Commission	Model Mines • Methods for Quantification of Benefits to Water ResourcesTable 4.2.1-5. p. 4-64 Table 4.2.1-5 discusses the method by which Benefits to water resources are quantitatively evaluated. The method involves finding an impact per million tons of coal based on the model mine production rate. The number from calculations based on the model mine is multiplied by total regional coal production in each year of analysis.A methodology based on model mine production rate is meaningless since the production rate is biased toward larger mining operations. Results of the analysis reflecting improved stream miles. improved forest acres and other perceived Benefits of the proposed rule are based on the biased and subjective production figures. For example, page 4-67 states that site-specific information on the extent of downstream water quality effects is lacking and that OSMRE's analysis assumes the adverse effects of mining on water quality are present at least 6.2 miles downstream. This 6.2 mile figure taken from the abstract of the Petty. et al (2010) paper provides no substantiation for said figure.	OSMRE disagrees the statement that model mine production rate is biased toward larger mining operations. Anticipated production for each model mine was based on actual production from operating mines in the region and is intended to be an accurate representation of mines in that region. Please refer to Master Response on Model Mines Analysis for additional information on the variable considered in the development of the model mines. The EIS extrapolates findings of research, such as the Petty study, as appropriate to examine potential consequences of the alternatives and acknowledges the limitations that the current science presents. Please refer to Master Response on Water Quality Benefits for a discussion of the methodology used and the particular application of the Petty study in the analysis, and a detailed discussion of the approach used to incorporate regional differences into the methodology.
OSM-2010-0021-0049	Interstate Mining Compact Commission	Model Mines Analysis - Water Quality 4.1.2. p. 4-36 In the discussion of the existing conditions (section 4.2.1.1) which is the model base condition, there is little information provided or references cited about western mines. An exception to this lack of references is on page 4-49 under Chemical Effects on Surface Waters where there is a reference cite to Lowry et al. 1983, which indicates that acidity in western mines with higher alkalinity is usually neutralized. This single reference related to western mining sites contradicts the purported water quality impacts which are the focus of this proposed rulemaking.	OSMRE agrees that acid or alkaline mine drainage has different or lesser impacts in Western streams. As stated in the EIS, acid mine drainage "is relevant to mining nationwide, although not as prevalent in the western coalfields, where the geology, soils and hydrology provide high buffering capacity (alkalinity)." However, we note that heightened buffering capacity of Western streams, however, does not rule out other water quality impacts that may be associated with mining. These may include increased levels of total suspended solids, conductivity, as discussed in Chapter 3 of the EIS.
OSM-2010-0021-0049	Interstate Mining Compact Commission	Model Mines • Limitations of Model Mine Analysis4.2.1 t p. 4-67"Lacking site specific information on the extent of downstream water quality effects of mines, this analysis assumes, on average, that adverse effects of mining on water quality persist 6.2 miles downstream of mines for	The commenter is incorrect. A variety of site specific variables were used to in the development of the model mines that were developed from real mines and environmental conditions. For more

MODEL MINES

		streams that cross the disturbed area of a mine site."If the model mine analysis is based on hypothetical assumptions which cannot be validated by actual mine operations. the results of the analysis cannot be considered best available science. There are hundreds of actual mines with actual data that OSMRE has access to. Using hypothetical information when actual data is available does not qualify as the "hard look" required by NEPA.	information on this analysis please refer to Master Response on Model Mines Analysis.
OSM-2010-0021-0049	Interstate Mining Compact Commission	Model Mine Analysis • Limitations of Model Mine Analysis 4.2.1.4, p. 4-72 Likewise, a surface mine in the Northern Rocky estimated to fill nearly 35 miles of ephemeral streams. Mountains and Great Plains region is ... After admitting few studies document the assumptions used, the model still makes a quantitative assumption (filling nearly 35 miles of ephemeral streams); however the source of the assumption is not referenced.	The model mine analysis used assumptions on the drainage area for ephemeral streams developed through examination of actual permit data. The model mine prediction is that 35 miles of ephemeral stream would be mined through, not filled as stated in the comment.
OSM-2010-0021-0049	Interstate Mining Compact Commission	Model Mine Analysis -Model Mine Assumptions Table 4.2.1-7, 4.2.1. p. 4-68 The 7.2 streams intercepted by the model Northern Rocky mountains mine is not representative of mines in Montana, North Dakota or Wyoming. It is rare for mines in this area to mine through intermittent or perennial streams, which would require analysis under the AVF rules.	Table 4.2.1-7 lists the estimated number of streams that cross mine sites in each of the regions. We generated these figures by comparing USGS data on intermittent and perennial stream locations to the locations and extents of mines in each region. The estimated numbers of streams crossing mines in the western region are much higher than other regions simply because the mines themselves are much larger.
OSM-2010-0021-0049	Interstate Mining Compact Commission	Model Mine Analysis - Stream Impacts4.2.1.3, p. 4-62 through 4-70This section describes the scientific research referenced and the procedures used in calculating stream impacts/Benefits using the model mines on a per ton basis and then extrapolating the results across the coal producing regions based on total tons produced in the region. Page 4-66 includes a qualifying statement that a majority of the water quality research has been performed in the Appalachian Basin, and that the studies do not support an "explicit analysis" of the SPR's impact on downstream water quality. Then the author continues on to cite one particular study performed by Petty, et.al. on the Lower Cheat River in West Virginia where it was determined that the downstream effects from mining extend approximately 6.2 miles from the mine site. This 6.2 mile value is then used to calculate downstream	As noted by this comment, the text on p. 4-62 of the DEIS acknowledged that existing research does not provide the ability to directly calculate nationwide impacts expected from the SPR. This statement is merely an acknowledgement that the existing research was conducted for specific hypothesis under specific conditions, and that this research therefore does not directly address the effects the alternatives would have on every parameter or in every possible site condition where coal mining would occur nationwide. As with any analysis similar to the EIS, applying the results of research requires extrapolation of the existing study results to account for the varying factors that were not present in the specific study areas or that are not definable given the scale of

MODEL MINES			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		effects for all coal regions across the US without any apparent adjustments for the distinct differences in topography, geology or hydrology between the coal producing regions.	the action being analyzed. The EIS extrapolates findings of research, such as the Petty study, as appropriate to examine potential consequences of the alternatives and acknowledges the limitations that the current science presents. Please refer to Master Response on Water Quality Benefits for a discussion of the methodology used and the particular application of the Petty study in the analysis, and a detailed discussion of the approach used to incorporate regional differences into the methodology.
OSM-2010-0021-0060	Ohio Department of Natural Resources	References in the DEIS to remining are limited and are related to approximate original contour issues and in one instance, highwall elimination. It is not clear why remining issues are not germane to stream protection and improvement.	We agree that all future coal mining would be expected to incur increased costs under the SPR. Our coal market forecast includes all anticipated U.S. coal production for the study period. A specific highwall mine was not modelled in the model mines analysis.
NA	EPA	Page 4-29, 4-30, Table 4.0-18, 4-37: While the Model Mine approach is valuable for relative comparison of the alternatives across different regions of the U.S., also consider alternatives on smaller spatial scales because variability within regions and among mine locations can be high for some critical factors (e.g., geologic formations likely to produce selenium, AMD, etc.).	We agree that analysis at the mine level is important to understand. However, due to the broad geographic scope and timeframe for the analysis, we are unable to forecast conditions at every future mine site as part of this national-scale EIS. The 13 model mines across the seven major coal regions were developed in order to capture regional variability in terms of mining methods as well as regional context as much as was feasible.
OSM-2010-0021-0696	Murray Energy Corporation	Section 2.4.2.3, p. 2-17, second paragraph:"The allowable deviation in the postmining elevation could be no more than ±20 percent of the difference between the premining surface elevation and the premining bottom elevation of that lowest coal seam, with allowances for slope stability and minor shifts in the location of premining features."There could be situations based on strip ratio and swell factors where this would not be possible. This effectively eliminates the ability to surface mine in steep slopes because fills are necessary for the excess swelled material. It will also impact the ability to use newer technologies like highwall mining, which can recover larger percentages of coal with smaller footprints.	No change is required. The alternative already allows for the very considerations raised in the comment. Farther down on the same page the EIS states "Compliance with the ±20 percent tolerance is not practicable in contour mining on steep slopes (defined as slopes greater than 20 degrees) because of stability and equipment constraints. Therefore, the ±20 percent tolerance requirement does not apply to that portion of a contour mine permit where steep-slope mining is conducted. The tolerance and digital terrain modeling requirements also would not apply to remining sites, permits 40 acres or smaller in size, or operations that qualify for the thin overburden standards of 30 CFR 816.104."

MODEL MINES			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
OSM-2010-0021-0696	Murray Energy Corporation	OSMRE fails to explain why the 13 mine models developed in preliminary EIS work were not included in the DEIS….The mine models are integral to understanding the differences between mining regions and different mining practices	No change required. The model mine analysis was included for public review and comment within appendices B and C of the draft Regulatory Impact Analysis.
OSM-2010-0021-0696	Murray Energy Corporation	Alternative - Absolutely prohibit all surface coal mining and reclamation activities, including fill placement and coal mine waste, in or within 100 feet of all streams, including ephemeral, Section 2.6.1, p. 2-55 "According to the model mine analysis, implementation of this Alternative would significantly reduce production nationwide." Several studies in different U.S. mining regions and by the USGS have indicated that applying site-specific restrictions to estimates of available coal resources significantly reduces the amount of coal that is considered recoverable (see, e.g., Ellis et al., 2002; Luppens et al., 2009).	Thank for your comment. Please refer to Section 4.1 of the EIS for results of the analysis of the impacts of the rule alternatives on coal production.
OSM-2010-0021-0696	Murray Energy Corporation	The model mines approach subjectively applies models with larger production rates to most of the coal mines in the country, even where the majority of mines in a given region have lower production rates than the model mines. As a result, this method overstates the Benefits of the action alternatives, including Alternative 8, and overstates the issues arising from the No Action Alternative. It underestimates costs to mining companies and budgetary requirements of state programs for the action alternatives. Under the model mines approach, the bigger the mine, the cheaper it will be on a cost-per-ton basis to carry out extra monitoring and compliance duties. Therefore, the quantitative method developed in the action alternatives, including Alternative 8, is not based on real-world numbers.	The commenter is incorrect in stating that the model mines approach subjectively applies models with larger production rates. Anticipated production for each model mine was based on actual production from operating mines in the region and is intended to be an accurate representation of mines in that region. Please refer to Master Response on Model Mines Analysis for additional information on the variable considered in the development of the model mines.
OSM-2010-0021-0696	Murray Energy Corporation	Limitations and Uncertainties Section 4.0.4, p. 4-29, Table 4.0-18 The accuracy of the analysis is limited by many factors, including the use of model mines which are supposed to be representative of all mining operations across the U.S. If the model mine analysis cannot be calibrated to or validated by actual mine operations, it is of questionable value. It is unclear what types of model mines these are, and whether they are equally divided among the different types (surface and underground) and different extraction	Mining type and extraction methods are identified in Table 4.1-3 of the EIS. For more specifics of the model mines please refer to Appendix B of the RIA. Additionally, the model mine analysis is based on actual mine operations. Please refer to Master Response on Model Mines Analysis for additional details on this analysis. Furthermore, the model mine analysis was also peer reviewed by experts in the mining field.

MODEL MINES			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		methods. See Table 4.1-3. These questions should be addressed in this section.	
OSM-2010-0021-0696	Murray Energy Corporation	In Section 4.2.1.4 (DEIS, at 4-70), OSMRE states: "The engineering analysis found that direct stream impacts from underground mines were temporary; therefore, downstream improved miles from underground mines are not quantified." If direct stream impacts from underground mines are temporary, then the statement on page 4-49 is incorrect. The statement on page 4-49 is not supported by any data while the statement on page 4-70 appears to have some analysis behind it. Therefore, the statement on page 4-49 needs to be modified to reflect the lack of impacts found in the engineering analysis. There are also numerous scientific studies that have found that the potential dewatering impact on streams from underground mining is often temporary and streams can fully recover (Gill, 2000; Wade, 2008; Rauch and Evans, 2004).	It is unclear what statement on page 4-49 the commenter is referring to. However, with regard to temporary impacts to streams OSMRE clarified in the Final Rule that the definition of material damage to the hydrologic balance outside the permit area does not apply to temporary subsidence impacts from underground mining. The rule text was revised to ensure that temporary subsidence impacts to streams and other water resources are corrected or repaired within a two-year period. This clarification was in response to concerns that the Final Rule could be interpreted so as to prohibit underground mining operations that could result in temporary impacts to streams. No change in the EIS text is necessary.
OSM-2010-0021-0696	Murray Energy Corporation	The model mine analysis is poorly presented, difficult to understand, and not adequately documented. This is particularly important because much of the subsequent analysis and conclusions of the DEIS are based on this model mine approach. The level of detail provided in the DEIS is not adequate to understand or evaluate what the agency has done or how the values in the model mines were developed or used in the analysis. Further, the references provided, values presented, and conclusions reached are clearly biased to eastern Appalachian conditions and appear incorrect and misleading for western mines. The lack of fundamental site-specific data and inability to validate this model make its use problematic. Models must be calibrated to real-world conditions and validated by comparing model predictions to actual site conditions. This model has not been calibrated or validated, and, as such, does not meet the best available science criteria that NEPA demands. While models may be a useful component of a NEPA "hard look," this model appears to provide a path to a predetermined result rather than acting as a scientific tool that contributes to the understanding of environmental impacts of the Proposed Rule.	Thank you for the comment regarding the level of detail provided on the model mine analysis. Additional detail on how the model mine analysis was developed and how it accommodates regional differences has been provided in the FEIS (see section 4.1 and Appendix B to the RIA). OSMRE engaged a team of independent reviewers to provide an objective review of the analysis methodologies used in the EIS. A specific peer review of the model mines methodology was conducted by experts in the mining field.
OSM-2010-0021-	Murray Energy	Section 4.1.3, p. 4-38	The commenter is incorrect in stating that the

MODEL MINES			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
0696	Corporation	"To estimate the total compliance costs of an Action Alternative, the analysis first estimates the expected increase in operational and administrative cost for each of the thirteen model mines. The analysis then converts them to costs per ton of coal produced." Because most of the model mines are larger (have a higher production rate) than the majority of mines in a given region, economy of scale suggests the cost per ton would be underestimated for mines smaller than the model mine. In applying these lower costs per ton to determine production impacts in each region, the DEIS underestimates the impacts to production and administrative costs to both government and industry.	model mines are larger than the majority of mines in a given region. Anticipated production for each model mine was based on actual production from operating mines in the region and is indented to be an accurate representation of mines in that region. As such, OSMRE believes that reported impacts of the SPR are not underestimates. Please refer to Master Response on Model Mines Analysis for additional information on the variable considered in the development of the model mines.
OSM-2010-0021-0696	Murray Energy Corporation	More often than not, current practices involving mining activity through or beneath a stream result in a decrease in stream elevation, more or less equally across the surface topography. If the Preferred Alternative is required, it is possible that the stream and land along the 100-foot buffer zone will not experience the same drop in elevation affecting the land surrounding the stream and buffer zone. If this occurs, the stream and land along the buffer zone may become perched at elevations higher than the surrounding land. The consequence may be an impact to hydrological conditions greater than the impact associated with mining activity through or beneath a stream....The stream loss in this case would likely be permanent. OSMRE should examine the hydrological consequences of this scenario and determine whether this scenario is a plausible outcome of its Preferred Alternative.	Thank you for the comment. The scenario expressed is not a plausible outcome of any of the alternatives, including that of the No Action Alternative. Design standards required by existing regulations require positive drainage to receiving streams; operations that would propose to do otherwise would not be permittable under existing regulations.
OSM-2010-0021-0696	Murray Energy Corporation	Results of Quantitative Analysis of Surface Water Impacts Section 4.2.1.4, p. 4-72, "Mined through streams" bullet "For instance, a typical surface mine in the Illinois Basin is estimated to create about nine miles of mined through ephemeral stream. Likewise, a surface mine in the Northern Rocky Mountains and Great Plains region is estimated to fill nearly 35 miles of ephemeral streams." OSMRE fails to provide supporting references and data. OSMRE fails to specify a definition of representative, or the "typical", Illinois Basin stream. OSMRE fails to specify a definition of the "typical" Northern Rocky Mountains and	An in-text citation to RIA Appendix B has been added to the text. The appendix describes the data sources and references used to construct the Model Mines analytical framework to quantify the impacts of mining through streams.

MODEL MINES			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		Great Plains region data.	
OSM-2010-0018-10385	Wyoming County Commissioners Association	Only one of the 13 model mines represents coal mining in the Powder River Basin (PRB) in an area the analysis calls the "Northern Rocky Mountains and Great Plains." This area includes not only the PRB, which by itself produces nearly 40% of all the coal in the United States, but also mines in Montana and North Dakota. Given the size and scale of PRB mines, the analysis is immediately flawed by failing to include a PRB-specific mine for analysis. Further, the "representative" mine for the Northern Rocky Mountains and Great Plains falls woefully short of a realistic mine.	The model mine does include a Powder River Basin (PRB) mine. It is assigned to the Northern Rocky Mountains and Great Plains Region. The goal of the Model Mine analysis was to design mines that are representative of the majority of operations located in each region. However, actual individual mining operations will vary in practice based on specific factors such as topography, geology, and hydrology. Active mine permits with similar annual production tonnages to the regional representative tonnages were reviewed as part of development of the model mines. The model mine analysis uses design elements from these currently operating mines. These permits were used to define coal seam thicknesses, life of mine coal reserves, depth of cover and stripping ratios, stream impacts, mine impact acreage, reclamation plans, and other pertinent information related to each operation. The geographic location of each active permitted operation was also used to identify a realistic mining location for each model mine. The proximity of the model mines to the associated permits ensured the terrain and geology of the model mine operation mirrored the permits. Additional discussion of the model mines development process has been added to the FEIS and RIA.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.1.4, p. 4-72, "Mined through streams" bullet Likewise, a surface mine in the Northern Rocky Mountains and Great Plains region is estimated to fill nearly 35 miles of ephemeral streams. After acknowledging that there are few studies that document the assumptions used the model, OSMRE still makes a quantitative assumption, and the source of the assumption is not referenced.	An in-text citation to RIA Appendix B has been added to this section. The appendix describes the data sources and references used to construct the Model Mines analytical framework to quantify the impacts of mining through streams.
OSM-2010-0021-0049	Interstate Mining Compact Commission	Model Mine Analysis • Haulage Costs Section 5.1, p. B-32 The model presumes that the largest incremental operating cost will be for additional haulage associated with building excess spoil fills in four-foot lifts. OSMRE seems to ignore the additional costs associated with building isolation zones in the backfill for inimical	The commenter is not correct about the assumptions in the analysis. In fact, the haulage costs include all costs to build excess spoil fills in 4-foot lifts, including creating a stable fill in a steep slope area, include over stacking, placement and cycle times, compaction and consolidation, and reclamation of haul roads.

MODEL MINES			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		materials (acid and toxic forming); the added costs for building stable fills in steep slope areas (compaction and consolidation); and the added haulage costs when building reclaimed areas to a more natural and diverse profile (longer cycle times for spotting trucks). These missed costs become even greater if the reclamation profile is to include over stacking: placement and cycle times, compaction and consolidation, reclamation of haul roads.	
OSM-2010-0021-0060	Ohio Department of Natural Resources	Chapter 3, 3.1.6.3 Coal Refuse Disposal Facilities, Page 3-30, 2nd Paragraph "More than 90 percent of the documented wells reported are in four states: Ohio (3570), Idaho (575), West Virginia (401), and North Dakota (200) (U.S. EPA, 1999)." This appears to be an inordinately high number for Ohio when compared to other coal producing states.	This value was extracted from page two of U.S. EPA 1999. For additional information related to the state and U.S. EPA Regional survey, please see: https://www.epa.gov/sites/production/files/2015-08/documents/classvstudy_volume10-minebackfill.pdf.

14. Underground Mining

UNDERGROUND MINING			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
OSM-2010-0021-0059	CONSOL Energy	The DEIS assumes that only coal mines that will have permanent adverse impacts to streams will be denied permits. This is not what is reflected in the SPR. Under the proposed SPR, coal mines that have the potential to cause adverse impacts to streams (including subsidence from underground mines), will not be permitted or have existing permits renewed. The proposed SPR places the burden of proof on the permit applicant to prove that there is no potential impact to the stream or the " adjacent areas" from the coal mining. However, the requirements placed upon this burden of proof are such that a coal mine permit applicant will never meet them, especially given the confusion this causes for state regulatory agencies. This essentially strands all coal reserves under streams and within the "adjacent area" to streams. [...] Inconsistencies such as this call into question the validity of the DEIS.	OSMRE has clarified in the final rule that not all of impacts would necessarily rise to the level of material damage to the hydrologic balance outside the permit area, especially ones of a temporary nature. Therefore the analysis of the EIS and the SPR do not conflict.
OSM-2010-0021-0059	CONSOL Energy	The DEIS fails to properly consider the major difference between surface coal mining and underground coal mining as required by SMCRA.	Thank you for your comment. Please refer to Master Response on Alternatives.
OSM-2010-0021-0049	Interstate Mining Compact Commission	Simplified Assumptions • Effects of Action Alternatives on Coal Production 4.1.4, p. 4-42, Table 4.1-5 The effect of the action alternatives on coal production is based on assumptions that do not account for full implementation of the rule. For example, OSMRE's analysis "does not anticipate that the rule would reduce the overall volume of longwall mining activity" (see Exhibit ES-1A, Draft Regulatory Impact Analysis). This conclusion is based upon OSMRE's finding that "significant underground mineable reserves exist in areas where material damage to the hydrologic balance (permanent stream loss)" would not be expected to occur. Yet the proposed rule's definition of material damage to the hydrologic balance sets a threshold for damage that is much lower than permanent stream loss.	OSMRE clarified in the Final Rule that the definition of material damage to the hydrologic balance outside the permit area does not apply to temporary subsidence impacts from underground mining. Please refer to Master Response on Material Damage to the Hydrologic Balance for additional detail.
OSM-2010-0021-0049	Interstate Mining Compact Commission	Model Mine Analysis - Water Resources4.2.1.4. p. 4-70The engineering analysis found that direct stream impacts from underground mines were temporary. There is no detail	The referenced engineering analysis is detailed in Appendix B to the Regulatory Impact Analysis for the SPR, which is included as part of this rule

UNDERGROUND MINING			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		provided regarding the engineering analysis referenced in this paragraph, but it does not appear to be in reference to the model mine approach. OSMRE must provide the engineering analysis referenced, as this is a significant finding. Failure to provide the engineering analysis shows a lack of transparency in OSMRE's analysis.	package.
OSM-2010-0021-0060	Ohio Department of Natural Resources	Chapter 4, Page 4-70, Streams, 3rd Bullet, Downstream miles experiencing improved water quality "The engineering analysis found that direct stream impacts from underground mines were temporary; therefore, downstream improved miles from underground mines are not quantified." This statement does not distinguish between room and pillar and longwall mining, but does appear to acknowledge that underground mines may not have downstream impacts and those impacts that do occur may not be long-term.	Thank you for your comment.
OSM-2010-0021-0696	Murray Energy Corporation	Accordingly, should OSMRE decide to include underground mining in a Proposed Action, it should evaluate an alternative that proposes a different regulatory approach that is tailored to the characteristics and the documented impacts of underground mining operations.	The comment is correct that 30 U.S.C. 166(a) requires that the Secretary promulgate rules and regulations directed toward the surface effects of underground coal mining operations, and further that it requires the Secretary to consider the distinct differences between surface coal mining and underground coal mining. The alternatives presented in the DEIS accomplished this requirement, making evaluation of a separate alternative focused on just underground mining unnecessary. Considerations for the unique aspects of mining are incorporated throughout the alternatives. For example under all alternatives the proposed definition of "adjacent area" would account for the potential impacts from subsidence that may occur as a result of underground mining activities. The proposed definition would also account for the potential for underground mining to result in the formation of mine pools, mines that act as a single hydrologic unit after being filled with water through surface recharge. For example, the new definition would include any areas that could be affected by landslides or blowouts resulting from mine pool formation.Additionally, under Alternatives 2, 3, 4

UNDERGROUND MINING			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
			and 8 the proposed definition of "material damage to the hydrologic balance outside the permit area," which is distinct from the previously discussed definition of "material damage," includes language that expressly applies the definition to underground mining activities and to subsidence resulting from underground mining activities, except for damage that can be corrected under 30 CFR 816.40 (replacement of protected water supplies) and 817.121 (correction of subsidence damage to protected structures, lands, surface features, streams, etc.).Also unique to underground mining, the final Preferred Alternative includes the requirement that, if the permittee does not complete correction or repair of subsidence-related material damage to surface lands, waters, or protected water supplies within 2 years following the occurrence of that damage, the regulatory authority initiate bond forfeiture proceedings and use any funds collected to repair the surface lands and waters or replace the protected water supplies. This requirement would not apply if the landowner refuses to allow access to conduct the corrective measures.
OSM-2010-0021-0696	Murray Energy Corporation	The DEIS assumes that all underground mining will result in subsidence. The DEIS needs to more accurately describe the frequency and magnitude of these events.	The intent of EIS Chapter 3 is not to state that all subsurface mining results in subsidence. Section 3.1 illustrates surface effects of underground mining. In this chapter, OMSRE defines the mechanism by which subsidence occurs, the types underground mining that causes the surface effect, and common surface impacts attributable to subsidence. However, to address any potential misunderstanding, the first sentence in the section has been reworded to state that removing adequate underground support for overburden can result in surface collapse, or subsidence.
OSM-2010-0021-0696	Murray Energy Corporation	The Proposed SPR will significantly limit the area that can be mined by longwall methods, despite the fact that subsidence impacts are currently highly regulated. Subsidence, as a result of longwall mining, is predictable and planned. Currently, states require mine subsidence control plans before any mine is permitted. Additionally,	OSMRE clarified in the Final Rule that the definition of material damage to the hydrologic balance outside the permit area does not apply to temporary subsidence impacts from underground mining. Please refer to Master Response on Material Damage to the Hydrologic Balance for

UNDERGROUND MINING			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		mining companies are required to conduct significant land reclamation after mining to return the land to the premining condition. The DEIS fails to analyze the true impact of the Proposed SPR on longwall mining or to account for the associated costs and impacts.	more details
OSM-2010-0021-0696	Murray Energy Corporation	A one-size-fits-all approach to limiting mine operations to control impacts from subsidence is not appropriate. The degree of subsidence varies significantly based on a number of factors, such as local geology (geotechnics and structural geology), mine characteristics, and surface topography. Certain geographical areas are more prone to subsidence than others. The DEIS fails to analyze these variations.	Thank you for your comment. The variation in mining conditions is considered in the RIA and EIS. The model mine analysis takes into account numerous regional variations in topography, geology, and mine characteristics. Please refer to the Master Response on Material Damage to the Hydrologic Balance and the Master Response on the Model Mines Analysis. In addition, OSMRE clarified in the Final Rule that the definition of material damage to the hydrologic balance outside the permit area does not apply to temporary subsidence impacts from underground mining.
OSM-2010-0021-0696	Murray Energy Corporation	The long-term impacts on streams from subsidence related to underground mining are not well understood. Several studies have found short-term dewatering is followed by full recovery and possible net Benefits to the stream. The DEIS fails to analyze this area or explore the relevant literature.	No change is required. The statement regarding possible net Benefits appears to be speculative. In reviewing the studies cited it is unclear as to how dewatering caused by underground mining can result in net Benefits to the hydrologic balance.
OSM-2010-0021-0696	Murray Energy Corporation	OSMRE's characterization of requirements for underground mining is incorrect. The baseline monitoring requirements for groundwater, surface water, and geologic conditions for surface coal mining operations and underground mining operations are described with the assumption that underground mining can be viewed as analogous to surface mining when applying rules. As is made evident by Congress's distinct treatment, the two mining methods are completely different in technology, geography, potential impact, and mitigation strategies. The prescriptive baseline monitoring requirements related to groundwater and surface water quality (e.g., pH, total iron, and total manganese) and quantity and geologic conditions may or may not be relevant to a given underground or surface mining operation much less be the same for both.	No change is required. The comment has taken the referred to text from the executive summary of the DEIS out of context and has consequently misinterpreted this text. The baseline data required to assess the permit is independent of the mining type. The purpose of the baseline data collection is to assess the hydrology and geology of the permit area.
OSM-2010-0021-0696	Murray Energy Corporation	A fundamental flaw in OSMRE's analysis of action alternatives is that none of the alternatives are directly applicable for examining the impact of the Proposed Rule	Thank you for your comment. Please refer to Master Response on Alternatives.

UNDERGROUND MINING			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		on underground mining. Alternatives that address underground mining should be incorporated, or underground mining should be removed from the rule and the DEIS.	
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.1.1.1, p. 4-33; second paragraph, second and third sentences"In the near term, however, underground production is expected to grow temporarily because of the addition of several new longwall mines, peaking in 2024. Most of the drop in total underground production (62 percent) is anticipated in the Appalachian Basin region, where a decline of over 30 million tons between 2020 and 2040 is expected"Figure 4.1-3 (p 4-32) appears to show a slight rise until 2024, then a fairly steady production until 2034, followed by a decline for the Appalachian Basin. No reason is given for the decline in 2034. OSMRE should provide a table, in addition to the graph, to provide a better understanding of the actual quantities related to each year. Given the burden of the Proposed Rule, it would be difficult to predict a rise in the number of underground mines. Analyses of "confidential business information" of MEC, which is provided in another chapter of this comment document under "Economic Impact of the Proposed Stream Protection Rule (SPR) on Murray Energy Corporation Underground Mining Operations in the U.S." demonstrate that enactment of the Proposed SPR will severely curtail or totally eliminate longwall mining operations.	Due to rapidly changing conditions in the coal market, the baseline coal production forecast has been revised in the final RIA and EIS. Detailed tables depicting both the baseline coal production and the forecast production under the SPR are presented in Appendix F to the RIA.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.3.1, p. 4-133 "Coal mining permanently alters the geological structure of the mined area because of the removal of coal and, for surface mines, overburden. Factors that determine the level of geological disturbance are the elevation of the lowest coal seam mined, the depth of overburden above this seam, and the area mined. Surface mining completely alters the geologic structure above the lowest coal seam mined in that previously discrete strata of rock and soil, each stratum with its own distinctive characteristics, are converted to a more or less uniform fragmented mixture of rubble. Typically referred to as spoil, this rubble consists of mixtures of the parent rocks, with percentages of rock types varying at different locations across the site." This short section does not discuss the identification of acid-forming rocks through overburden analyses nor does it	Thank you for your comment. Text has been added to EIS Section 4.2.3.1 to include a description of the identification of acid-forming rocks through overburden analysis.

UNDERGROUND MINING			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		indicate that such acid-forming or toxic materials should be isolated in the backfill. Because this is current practice typically, its exclusion from the discussion portrays the mining process as more adverse than it is. OSMRE ignores current mining patterns that identify and separately backfill problematic strata.	
OSM-2010-0021-0696	Murray Energy Corporation	The Proposed SPR specifies that "the adjacent area for an underground mine includes both the area overlying the proposed workings and the area within a reasonable angle of draw from the perimeter of the underground workings. " The angle of draw, however, is not clearly defined in the Proposed SPR and is not defined in the DEIS.	Thank you for the comment. Please refer to the definitions within the rule at 701.5 where we have changed the "angle of draw" term to the "angle of dewatering" and defined the angle of dewatering to mean "the angle created from a vertical line drawn from the outer edge or boundary of high-extraction underground mining workings and an oblique line drawn from terminus of the vertical line at the mine floor to the farthest expected extent that the mining will cause dewatering of groundwater or surface water."
OSM-2010-0021-0696	Murray Energy Corporation	Need for Adequate Data Section 1.1.2, p. 1-13 OSMRE's Proposed Rule and the alternatives presented in the DEIS do not provide any clarity with respect to the types of information needed to address underground mining requirements to minimize disturbances of the prevailing hydrologic balance at the mine site and associated off-site areas and to water quantity.	Thank you for the comment. No change is required. The baseline data required to assess the permit is independent of the mining type (underground versus surface). The purpose of the baseline data collection is to assess the hydrology and geology of the permit area.
OSM-2010-0021-0696	Murray Energy Corporation	Alternative 1 (No Action Alternative) Section 2.4.1, p. 2-4, last paragraph There are several sections (e.g., 3.8.3.3 Aquatic Resources) where OSMRE discusses topics that appear not to be pertinent to the Proposed Rule, yet it is omitting a complete and detailed discussion of underground mining, which in some regions (e.g., Appalachia and Illinois basins) accounts for approximately 50% of the mining activities. The importance of this regulatory issue to the U.S. economy and the mining industry should preclude considerations of brevity and other conveniences in the DEIS. Underground mining has not been adequately addressed in this DEIS.	No change required. As discussed on page 1-3 of the DEIS, SMCRA defines surface coal mining and reclamation operations to include the surface effects of underground mining. 30 U.S.C. 1291. The environmental implications of the alternatives, including effects of the new requirements, on the surface effects of underground mining have been analyzed and are presented in the EIS and RIA.
OSM-2010-0021-0696	Murray Energy Corporation	Section 2.5, p. 2-43Requirements of surface coal mining operations and underground mining operations are described in the DEIS and Proposed Rule based on the	No change required. As discussed on page 1-3 of the DEIS, SMCRA defines surface coal mining and reclamation operations to include the surface

UNDERGROUND MINING			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		assumption that underground mining can be viewed as analogous to surface mining. It is evident that the two mining practices (surface and underground) are fundamentally different from each other with respect to technology, mining, operations, geography, environmental footprint, and mitigation strategies.	effects of underground mining. 30 U.S.C. 1291. The environmental implications of the alternatives, including effects of the new requirements, on the surface effects of underground mining have been analyzed and are presented in the EIS and RIA.
OSM-2010-0021-0696	Murray Energy Corporation	Alternative Comparison Discussion Section 2.5, p. 2-43 OSMRE fails to identify the rationale for preparing a DEIS that not only does not fully address underground mining, but also simplifies and generalizes all mining practices to a common operational, economic, social, and environmental scenario that treats surface and underground mining the same.	The commenter does not accurately summarize the methodology used by OSMRE in its EIS and RIA. As described in the analyses, 13 model mines were designed for purposes of the analysis, eight of which are surface mines, and five of which are underground mines (three longwall and two room and pillar mines). In addition, there are separate appendices that address longwall mining and coal refuse facilities in detail. Please refer to Master Response on Alternatives.
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.1.1.4,p. 3-7 There are a number of errors in OSMRE's assumptions on limits to recoverable reserves. For example, the authors state that the minimum thickness that can be mined by surface methods is 1 foot. This statement ignores the use of fine graders to extract high-value, very thin seams that are less than 1 foot thick. The authors also say that the maximum thickness that can be extracted by underground methods is 15 feet. This statement ignores experimental high-seam longwall faces and the use of sublevel caving or a cut-and-fill longwall face. The estimated recoverable reserves analysis is flawed because it is based on current (2015) conditions and does not consider future developments. This is inappropriate because OSMRE's analysis is supposed to be for the period 2020-2040.	Chapter 3 provides data on the affected environment as it exists today. The analysis of impacts in Chapter 4 of the EIS considers the availability of reserves for future mining activities
OSM-2010-0021-0696	Murray Energy Corporation	Sections 3.1.2 - 3.15, pp. 3-9 to 3-26 These sections present significantly more information on underground mining than surface mining. This is especially true with respect to OSMRE's discussion of the degree of surface impacts and effects: the surface effects of underground mining and underground mine waste disposal are discussed in detail, while little to no discussion is presented regarding the negative effects of surface mining.	No change required. This section is a discussion of mining methods intended to familiarize readers with mining methods, and provides the appropriate amount of detail on each. Discussion of impacts related to surface or underground mining is contained within chapter 4.

COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.1.3, p. 3-11 to 3-17This section describing underground mining methods is misleading as demonstrated by the illustrations that are outdated and no longer accurate. For example, continuous miners used today do not dump cut coal on the floor (Figure 3.1-5, pg. 3-13 (149)).	Thank you for the comment. OSMRE has edited this section in the FEIS to more accurately reflect current mining activity.
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.1.6.2, p. 3-29 "Most underground mined coal must be processed, but some surface mined coal can be sold without processing. Coal mined by underground methods may contain up to 50 percent rock because of rock seam partings removed with the raw coal or because it is necessary to mine rock from the roof or floor to gain access height. Surface operations can often selectively mine the coal and remove waste rock without mixing the two; this is dependent on the geology and equipment used." If a coal seam is sufficiently thick, it is possible for underground mining operations to produce coal that is not mixed with an appreciable amount of waste rock. Additionally, under most applications, waste rock mixes with coal in surface mining operations. This description is unnecessarily biased, and presents underground mining as an inferior mining method with regard to waste, hi many instances surface operations remove a greater amount of waste rock than underground operations.	Thank you for the comment. We agree that in some situations where an underground mined seam does not have a binder and the roof and floor are competent, the continuous miner may be able to stay within seam and the coal would not need to be processed. Additionally some surface mined coals are processed to remove waste rock. OSMRE has edited this section to more accurately describe current mining and preparation practices, while providing for the unique instances of coal beneficiation.
OSM-2010-0021-0696	Murray Energy Corporation	*Section 4.2.3.1, p. 4-130* *Subsidence may reach the surface, depending upon the depth of the mine and the competence of rock strata between the underground workings and the surface. Subsidence that reaches the surface will alter the surface configuration and topography. Subsidence also can dewater streams in whole or in part.* Significant subsidence resulting from modern underground mining practices is rare, making OSMRE's discussion here inaccurate.	No change required. The text does not state or imply that subsidence is a frequent occurrence.
OSM-2010-0021-0696	Murray Energy Corporation	*Section 4.5.2.3, p. 4-337, first bullet* *Underground coal production is expected to grow in coming years, as the industry exploits stores of high-value metallurgical coal (met coal), working seams that would be unprofitable to mine at steam-coal prices.* OSMRE should remove underground mining from the	The final rule does not preclude any specific method of underground mining either directly (e.g., a prohibition of underground mining) or indirectly (e.g., make underground mining uneconomical or impossible). Our primary focus in the proposed rule was to clarify our position that the obligation to prevent material damage to

UNDERGROUND MINING			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		Proposed Rule. If export demands outweigh the decrease in U.S. demand (see DEIS, at 4-33-34), then coal will remain a valuable commodity that provides jobs and associated employment for the foreseeable future.	the hydrologic balance outside the permit area applied to areas overlying the underground workings of an underground mine, which is part of the adjacent area as that term is defined in section 701.5 of our regulations. Please see the discussion of underground mining and its inclusion in the rule within the rule preamble.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.2.1, pp. 4-89 through 4-91The information and discussion with respect to ecology focus on surface mining, and in particular, mountaintop mining and valley fills. OSMRE provides no information relevant to the impacts, if any, from underground mining.	The commenter does not accurately summarize the methodology used by OSMRE in its EIS and RIA. As described in the analyses, 13 model mines were designed for purposes of the analysis, eight of which are surface mines, and five of which are underground mines (three longwall and two room and pillar mines). In addition, there are separate appendices that address longwall mining and coal refuse facilities in detail.
OSM-2010-0021-0696	Murray Energy Corporation	Impacts of the No Action Alternative on Water Resources; Surface Water and Groundwater Effects Section 4.2.1.1, p. 4-49 In Section 4.2.1.4 (DEIS, at 4-70), OSMRE states: "The engineering analysis found that direct stream impacts from underground mines were temporary; therefore, downstream improved miles from underground mines are not quantified." If direct stream impacts from underground mines are temporary, then the statement on page 4-49 is incorrect. The statement on page 4-49 is not supported by any data while the statement on page 4-70 appears to have some analysis behind it. Therefore, the statement on page 4-49 needs to be modified to reflect the lack of impacts found in the engineering analysis. There are also numerous scientific studies that have found that the potential dewatering impact on streams from underground mining is often temporary and streams can fully recover (Gill, 2000; Wade, 2008; Rauch and Evans, 2004).	The analysis is internally consistent. The quoted statement simply states that underground mining operations can adversely affect surface waters. There are no quantities or lengths of impacts associated with this statement. The engineering analysis places temporal constraints on these adverse impacts and does not claim that there are no adverse impacts.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.1.1, p. 4-48, fourth paragraph, last sentence "The lack of a clear federal definition also contributes to variability among states, and even among permits, in what the regulatory authority might require of the applicant." The requirements necessary to protect against material damage to the hydrologic balance outside the permit area may very well differ from one state to another, or possibly	As discussed in the preamble to the final rule, a federal definition is necessary to provide guidance and clarity to the regulatory authorities as they define the term for their own jurisdictions. As discussed in more detail in the preamble to the proposed rule, our previous rules did not contain a definition of "material damage to the hydrologic

UNDERGROUND MINING			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		even from one permit to another. A single federal definition will not likely suit specific circumstances. There is no discussion in this section of how Alternative 8, or any other action alternative, will address the perceived problem of variability among states and permit requirements.	balance outside the permit area," and, in the more than 30 years since SMCRA's enactment, very few states have adopted a definition.[20] As a result of the lack of a definition, what constitutes "material damage to the hydrologic balance outside the permit area" varies greatly. This has led to differences in enforcement across the country.
OSM-2010-0021-0056	Utah Mining Association	OSMRE treats surface mining the same as underground mining, which is inappropriate given that the two mining methods are not remotely comparable and have completely separate geographic, engineering, social, and economic aspects. The DEIS is deficient because it fails to evaluate an alternative that provides different regulatory approaches to the two distinctly different mining methods; a distinction that Congress drew in its construction of SMCRA.	The commenter does not accurately summarize the methodology used by OSMRE in its EIS and RIA. As described in the analyses, 13 model mines were designed for purposes of the analysis, eight of which are surface mines, and five of which are underground mines (three longwall and two room and pillar mines). In addition, there are separate appendices that address longwall mining and coal refuse facilities in detail.
OSM-2010-0021-0060	Ohio Department of Natural Resources	The DEIS does not recognize the distinct differences between underground mining and surface mining and the impact the proposed stream protection rule will have on coal extraction in general. The RIA projects the only impacts that will affect longwall mining operations are those associated with reforestation and projects essentially no impact to highwall mining operations.	The commenter does not accurately summarize the methodology used by OSMRE in its EIS and RIA. As described in the analyses, 13 model mines were designed for purposes of the analysis, eight of which are surface mines, and five of which are underground mines (three longwall and two room and pillar mines). In addition, there are separate appendices that address longwall mining and coal refuse facilities in detail.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.1.4, p. 4-70, first bullet OSMRE presumes surface mining only has surface impacts to water. Underground mining in Appalachia almost always has associated water permits.	The text cited by the commenter describes the impacts of SPR implementation by mining operations on surface waters. The commenter is correct that the focus of the section is on understanding the implications of changes to surface mining operations due to the SPR. This is because surface mining operations are anticipated to be primarily affected by the rule (Only 12 percent of compliance costs to coal mining activities are anticipated to be related to underground mining). Nonetheless, some additional text recognizing that underground mining operations may also affect surface waters

			under the No Action Alternative has been added to the FEIS.
OSM-2010-0021-0696	Murray Energy Corporation	Results of Quantitative Analysis of Surface Water Impacts Section 4.2.1.4, p. 4-70, third bullet "The engineering analysis found that direct stream impacts from underground mines were temporary; therefore, downstream improved miles from underground mines are not quantified." OSMRE's observation that underground mining contributes only temporarily to water quality impacts strongly suggests that the Proposed Rule should not apply to underground mining.	Please refer to the preamble of the rule for discussions of the rule's applicability to underground mining.

15. Alaska

ALASKA			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
OSM-2010-0021-0057	Alaska Dept. of Natural Resources	Pg. 3-243, Section 3.7.3.6 This section states there is no specific land use data available for the Healy Valley area. The Alaska Division of Mining, Land and Water maintains planning documents for areas where coal mining is active. It appears the DEIS did not make an effort to review this plans. The state has no record in the DEIS of this information being requested or reviewed: htpp://dnr.alaska.gov/mlw/planning/areaplans http://dnr.alaska.gov/mlw/planning/areaplans/tanana/pdf/sub4_managemen t_intent.pdf http://dnr.alaska.gov/mlw/planning/areaplans/tanana/pdf/sub4d.pdf http://dnr.alaska.gov/mlw/planning/areaplans/sumat/pdf/smap_2011_ch3_gl enn_hwy.pdf	Information on the land use in Tenana Basin Subregion 4 has been included in sections 3.7.3.6 and 4.7.3.6 to better characterize the region surrounding the Usibelli Coal Mine operations.
OSM-2010-0021-0057	Alaska Dept. of Natural Resources	Alaska is included in the “Northwest” Region along with Washington and Oregon. Reasoning for this breakdown is described more fully in Section 3.2.6 on page 3-83. Section 3.2.6 states that there are no current or proposed coal extraction mine permits in Oregon or Washington. I don’t believe this is correct as the John Henry mine in Washington has been proposed for reopening. Because of the extraordinary differences in its affected environment due to its sheer size and geographic separateness from Oregon and Washington, Alaska should be separated out into its own chapter. For example, Alaska has a variation in climate zones that are not adequately consider in the DEIS.	OSMRE acknowledges that there was a comment period in May of 2014 for an EA associated with the Pacific Coast Coal Company's proposal to reopen the John Henry Mine (http://www.wrcc.osmre.gov/initiatives/johnHenryMine.shtm). However, no additional information is available to support if the coal mine would reopen or when this could occur. As discussed in Sections 3.1 and 3.2.6, the SPR analysis centers on the currently active coal mining field for the Northwest Region, which is located in Alaska. Additional information on the variations in climate has been added to Chapter 3.
OSM-2010-0021-0057	Alaska Dept. of Natural Resources	Pg. 3-101, Section 3.3.7 Section breaks the soils in Alaska down into three ecoregions but does not reference a figure or map depicting the boundaries of these three ecoregions. Also completely leaves out the northwest arctic ecoregion.	Thank you for the comment. The text in this section has been edited and a figure has been added. The northwest arctic region is not included since the discussion and analysis centers exclusively on the active coal mining operations in the state of Alaska.
OSM-2010-0021-0057	Alaska Dept. of Natural Resources	Pg. 3-122, Section 3.4.2.6Even for the active mining area the description is minimal and incomplete. Compared to the description for the other regions, little is presented about the physical characteristics, geologic history and climate. In addition, the DEIS states there are two coal fields in Alaska	Thank you for the comment. Chapter 3 of the FEIS has been updated to provide additional information the Nenana and Matanuska coal fields.

ALASKA			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		but goes on to lump them as the interior coal fields even though the Matanuska coal field is in South Central Alaska and is a completely different climatic, physiographic and geologic setting then the Nenana Coal fields.	
OSM-2010-0021-0057	Alaska Dept. of Natural Resources	Pg. 3-123, Section 3.4.2.6 Figure does not cover all of Alaska's coal fields. Suggest they use or "Map of Alaska's Coal Resources Compiled by R.D. Merritt and C.C. Hawley, 1986: or similar source. http://pubs.dggsalaskagov.us/webpubs/dggs/sr/oversized/sr037_sh001.pdf	Figure 3.1-29 includes all the coal fields in Alaska. Figure3.4-12 was revised to further clarify that the discussion centers on the Nenana and Matanuska coal fields. The Merritt and Hawley map includes areas that are not expected to support active mining in the study timeframe and is therefore overly inclusive.
OSM-2010-0021-0057	Alaska Dept. of Natural Resources	Pg. 3-131, Section 3.5.2 Only discusses the Yukon River Basin and the Healy Valley streams. Does not address the Matanuska or any other part of the Cook Inlet in terms of Water Resources and they are quite disparate from Healy.	The discussion in section 3.5.2 includes Matanuska. No coal mining is currently occurring, or is reasonably foreseeable in the area of the Cook Inlet. See the Master Response on Alaska.
OSM-2010-0021-0057	Alaska Dept. of Natural Resources	Pg. 3-133, Section 3.5.2.3 Was all of Alaska used in the determination of stream lengths, or just the Tanana Basin? If it's statewide, those numbers seem low.	OSMRE has recalculated the stream length numbers to verify their accuracy. The stream lengths reported here are the lengths that fall within the study area determined by the active coal fields, and are not statewide.
OSM-2010-0021-0057	Alaska Dept. of Natural Resources	Pg. 3-2, Section 3.0.2 The chapter states there are only two areas with active or reasonably foreseeable mining. However, PacRim Coal has submitted two applications for a mine and associated facilities in the Beluga Coal Fields within Cook Inlet Basin. While the latest application was recently submitted the initial application was submitted to AKDNR in December 2012. This area has been in the stages of the permitting process since well before 2012 and to ignore its potential and exclude it from the Affected Environment section (estimated reserves ~2.3 billion short tons subbituminous; measured reserves 275 million short tons; DGGS publication 1986) discounts an area with a substantial amount of coal reserves for the Northwest Region.	OSMRE acknowledges the submitted permit application for the Beluga Coal Fields within the Cook Inlet Basin. However, given the uncertainty of a tentative approval and length of time to establish necessary coal mining infrastructure, coal production outside of Nenana and Matanuska are not considered in this analysis. For additional information, please refer to Master Response on Alaska and Sections 3.1 and 3.2.6 of the DEIS for clarification on the study area.
OSM-2010-0021-0057	Alaska Dept. of Natural Resources	Pg. 3-228, Section 3.6.2.6 Only lists one Federal Class I Air Quality Area, Denali National Park. There are very likely others such as Lake Clark National Park.	According to U.S. EPA, Alaska has four Class I Air Quality Areas (https://yosemite.epa.gov/r10/airpage.nsf/f3f22921988a261b882569e5005ee8bb/1cf6e1d33616e73988256a0800614727!OpenDocument): Denali National Park including Denali Wilderness, Bering Sea National Wildlife Refuge, Simonov

ALASKA			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
			National Wildlife Refuge, and Tuxedni National Wildlife Refuge. The other three Class I Air Quality Areas are sufficiently removed from active coal field operations. A new figure was added to the EIS for clarification.
OSM-2010-0021-0057	Alaska Dept. of Natural Resources	Pg. 3-343, Section 3.10.7 Tables I-26 through I-29 referenced in this section and found in Appendix I are very incomplete and do not list numerous state parks, national parks, and other significant public recreation and refuge lands within Alaska.	Thank you for the comment. OSMRE has corrected Appendix I Tables 26-29. Please see Tables I 1-3 for a summary of total national and state park visitations, park acreages, and revenues for Alaska.
OSM-2010-0021-0057	Alaska Dept. of Natural Resources	Pg. 3-344, Section 3.10 "The coal fields in the Southcentral region fall mostly on the Kenai Peninsula…." This statement is incorrect. There are also the Southcentral coal fields of Beluga, the Susitna Basin and Matanuska.	The discussion is focused on certain coal fields as described elsewhere in chapter 3. This point is clarified in the FEIS.
OSM-2010-0021-0057	Alaska Dept. of Natural Resources	Pg. 3-344, Section 3.10.7.1 Figure 3.10.6 does not include Denali State Park or Kachemak State Park (Kachemak is mentioned in the description). Chugach National Forest and Kenai National Wildlife Refuge are also both mentioned in the description but not depicted on Figure 3.10-6. Exit Glacier is part of Kenai Fjords National Park and does not require a separate listing. Other public lands of note that are missing include the Susitna Flats, Palmer Hay Flats, Goose Bay, Anchorage and Trading Bay State Game Refuges. No figures have been included of the Interior or Far North region and their respective public parks, recreation and refuge lands.	Figure 3.10.6 is not referenced for the park locations, a new figure to clarify the locations of the parks in the coal producing region has been added as Figure 3.10.6.1
OSM-2010-0021-0057	Alaska Dept. of Natural Resources	Pg. 3-352, Section 3.11.2.6 No mention of the proposed Chuitna mine or the mines at Wishbone Hill and Jonesville.	The statement refers only to active coal mine operations in Alaska because the SPR analysis centers only on active mining operations. Wishbone Hill permits were vacated by the US District Court of Alaska on July 7, 2016. Jonesville is permitted but not active, and the Chuitna mine is not yet permitted. Discussion of future potential mining has been clarified in the discussion of cumulative impacts.
OSM-2010-0021-0057	Alaska Dept. of Natural Resources	Pg. 3-445, Section 3.14.2.6 States that there is minimal data available for employment and payroll in the region. This is not correct. http://labor.state.ak.us/; http://www.usibelli.com/McDowell-Report-StatewideSocioeconomicImpacts-of-UCM-2015I.pdf;	OSMRE appreciates the materials provided by AKDNR. These sources validate our statement there is indeed minimal data available related to the employment and annual payroll for coal producing counties. Alaska wage data (Alaska.gov labor statistics) are organized into

ALASKA			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		http://www.usibelli.com/EEICreport.pdf	four categories: Fairbanks, Anchorage, Southeast, and Balance of State (all other areas). Unfortunately, these data do not provide sufficient resolution to estimate coal-producing county specific wage data.
OSM-2010-0021-0057	Alaska Dept. of Natural Resources	Pg. 3-453, 3.14.3 Lists six "Alaska Native Village Statistical Areas (ANVSA) within the study area for this analysis." The six villages listed for the analysis are Atqasuk, Chickaloon, Knik, Ninilchik, Tyonek and Wainwright. Unclear if they used these six villages as a statistical sample for all the coal regions in the Alaska or if they consider these six the only Alaska Native communities to potentially be affected by the Action Alternatives. If it is the latter there are many more communities to include and consider.	OSMRE acknowledges that there are many native communities in Alaska. However, this analysis only considered those communities within the model mines study area. The study area for the state of Alaska is the coal-producing region highlighted in Figure 3.14-15 and discussed in Section s 3.1 and 3.2.6.
OSM-2010-0021-0057	Alaska Dept. of Natural Resources	Pg. 3-50, Section 3.1.8.6"The Northwest region contains bituminous and lignite resources in Alaska." This is incorrect. Alaska contains lignite, sub-bituminous, bituminous and anthracite coal resources. http://www.dggs.alaska.gov/pubs/id/2636	The text has been updated to state that Alaska contains bituminous, sub-bituminous, lignite, and anthracite coal resources.
OSM-2010-0021-0057	Alaska Dept. of Natural Resources	Pg. 3-83, Section 3.2.6 There is more than a single operating mine in Alaska. UCM has five mines in the Healy area that are either extracting coal or actively being reclaimed.	According to the UCM website (www.usibelli.com): "…currently the only operational coal mine in the state of Alaska…" The text from UCM affirms that the Usibelli Mine is the only active coal producing operation in the Nenana Coal Field, and Usibelli Mine holds five active permits in the Nenana Coal Field.
OSM-2010-0021-0057	Alaska Dept. of Natural Resources	Pg. 3-84 to 85, Section 3.2.6 This section only discusses Central Alaska and Southern Alaska coal field geology and completely leaves out the Arctic Foothills Sub province and Arctic Coastal Plain Sub province.	OSMRE acknowledges the presence of coal reserves in the Arctic sub provinces. However, the section discusses the regions in Alaska where there are established coal fields. Expanding the discussion to include the northern regions would include areas that do not include active coal mining..
OSM-2010-0021-0057	Alaska Dept. of Natural Resources	Pg. 4-223, Section 4.3.1 States that the coal severance tax in Alaska 2012 was $40,696. According to the McDowell Group report "Statewide Socioeconomic Impacts of Usibelli Coal Mine, January 2015" prepared for UCM the Denali Borough generated approximately $100,000 from $0.05 per ton severance tax levied on coal and limestone extraction in	Thank you for your comment. The original value listed ($40,696,000) was total mining severance tax for the state of Alaska. This value was updated with the severance tax value listed in the 2015 socioeconomic analysis for UCM provided by AKDNR. While still an overestimate as this severance tax value includes some

ALASKA			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		2013. UCM paid nearly all of this tax.	contribution from limestone, the $100,000 value better represents coal related severance tax than the total mining severance tax for Alaska.
OSM-2010-0021-0057	Alaska Dept. of Natural Resources	Pg. 4-231, Section 4.3.1.8 Footnote #44. "Potential increases in employment related to compliance activities may mitigate the adverse impacts associated with production-related employment changes." In plain English this appears to translate to "More government jobs required for permitting and regulatory oversight may offset the number of jobs lost from private sector mining." In Alaska's current budget climate this is not necessarily an option to include regulatory personnel without outside sources of money.	The text says "Potential increases in employment demand related to compliance activities may mitigate the adverse impacts associated with production-related employment activities." The term "compliance-related" refers to industry's additional employment to achieve compliance as a result of the Rule. There were no government jobs reported in the RIA. The text in this section was revised to clarify industry costs in relation to regulatory costs.
OSM-2010-0021-0057	Alaska Dept. of Natural Resources	Pg. 4-267, Section 4.3.3.1 "The Northwest region has relatively little federal and state land and relatively few river miles within the study area. "This entire paragraph and it description of recreational activities and public lands used for recreation in Alaska is incorrect and incomplete. Entire section for this chapter on the Northwest region requires more complete research and information gathering by the preparers and contributors. Resources for more complete information include among others the NPS Regional Office in Anchorage and the State of Alaska Department of Natural Resources and the Department of Fish and Game.	. Thank you for your comment. EIS Section 4.3.3.1 has been revised to include a more accurate description of the recreational resources in the Northwest region.
OSM-2010-0021-0057	Alaska Dept. of Natural Resources	Pg. G-16, Appendix G.1.6Vegetation section does not include Interior or Arctic Alaska. http://www.adfg.alaska.gov/index.cfm?adfg=lands.main	This text, including the Northwest Regions sections of Chapter 3, have been updated to include both the Interior and South Central areas of Alaska.
OSM-2010-0021-0057	Alaska Dept. of Natural Resources	Pg. G-17, Appendix G.1.7 The fauna section is inaccurate and does not contain the many of the major terrestrial wildlife found in the coal producing regions including Moose (Laces alces), Brown (Ursus arctos) and Black (Ursus americanus) bear. http://www.adfg.alaska.gov/index.cfm?adfg=animals.main	OSMRE acknowledges that these species should be included in the Appendix G text and the recommendations have been added. The recommended species have also been added to section 3.8.8
OSM-2010-0021-0057	Alaska Dept. of Natural Resources	Pg. H-3, Appendix H "Acreage numbers for wetlands in AK should be fact checked. Appear to be undercounted."	The numbers are approximate but are correct as presented. The wetlands data represented here in Appendix H is only for the portion of AK included within the study area and not for the entire state.

COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
OSM-2010-0021-0057	Alaska Dept. of Natural Resources	Pg. I-2 Appendix I Dollar numbers should probably be fact checked.	No change required. The dollar figures of appendix I are from outside sources.
OSM-2010-0021-0057	Alaska Dept. of Natural Resources	Pg. I-33, I-34. Appendix I. Missing several state parks, national parks, wildlife refuges. The acreages listed are also highly suspect. For example, the acreage for Denali State Park in Table I-28 is shown as 1,605.31. The actual acreage for DSP is over 200 times bigger than this. According to Alaska State Parks DSP is 325,240 acres.	The areas presented are only those that intersect the study area, and in some instances of the text the text is reporting the acreage that falls within the study area versus the total acreage of the area in question. However, the comment is correct that errors were present in Appendix I and the text. This work has been redone in the FEIS.
OSM-2010-0021-0057	Alaska Dept. of Natural Resources	Pg. J-20, Appendix J These numbers look somewhat incomplete. The Alaska DNR Water Section may have more complete information.	For consistency within the EIS, the same sources (USGS, 2010, and Kenny et al., 2009) and years were used to report groundwater usage for all regions including the Northwest.
OSM-2010-0021-0057	Alaska Dept. of Natural Resources	Pg. 4-37, Section 4.1.2 This section states the only operating mine (UCM in Healy) is representative of coal production in Alaska. This completely ignores the two mines permitted in Matanuska Valley and the one currently in the permitting process in the Beluga Coal Fields. The geography, ecology, and watersheds are all varied from each other and to ignore that does not adequately represent the Alaskan environment.	As discussed in Section 3.1 and 3.2.6, the uncertainty of when coal mining operations could commence on the Matanuska Valley and the Beluga Coal Fields mines, therefore the analysis assumes that UCM's operating coal mine is representative of current and future geographies of coal mines in the Northwest.
OSM-2010-0021-0064	Alaska Coal Association	The DSEIS and RIA and incomplete – This is true specifically as they relate to Alaska. In light of the background information presented above, Alaska was only analyzed with two potential areas for coal development (Healy and the Matanuska Coal Field). This does not even include the Beluga Coal Field, which has an ongoing SEIS and permit applications on file to which OSM has tendered technical assistance in reviewing. Any potential impacts of this proposed rule as it relates to Alaska are significantly under-reported.	Please refer to Master Response on Alaska.
OSM-2010-0021-0065	EARTHJUSTICE * COOK INLETKEEPER	The DEIS does not adequately address the potential impacts of the proposed Rule to Alaskan salmon streams, nor to the communities and ecosystems in which salmon play a critical role. In its FEIS, OSMRE should consider the impacts of the Rule and alternatives on surface coal mining that would mine through or otherwise affect the salmon spawning streams that are so significant to Alaska's economy,	OSMRE acknowledges and appreciates the ecological, economic, human use, and recreational value of salmon and other anadromous fishes in Alaskan streams. The Action Alternatives of the Stream Protection Rule, including the Preferred Alternative, would require increased baseline data collection and

ALASKA			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
		culture, and environment. (in same packet is some attached literature about salmon and streams)	analysis, increased monitoring during reclamation, and prohibit mining activities within 100 feet of streams unless certain criteria are met. The analysis of the Action Alternatives generally indicates beneficial impacts to biological resources and topography, geology, and soils across all regions (please see section 4.0.3 of the EIS). The analysis identifies impacts between the existing rule and the Proposed Rule. Because coal production in Alaska is low, the Action Alternatives will have little impact relative to current regulations. Please refer to the Cumulative Impacts section of EIS Chapter 4 (section 4.5) for a discussion of the impacts of the Action Alternative relative to the No Action Alternative.
OSM-2010-0021-0069	Alaska Miner Association	Alaska, despite having immense coal reserves, does not appear to be considered in the Proposed Rule documentation. No scientific studies relevant to Alaska are referenced, and no public meetings were held in Alaska. The Alaska specific details that would result from study and a request for comments would have demonstrated the uniqueness of Alaska and the inappropriateness of the proposed regulations.	Please refer to Master Response on Alaska, which describes OSMRE's consideration of Alaskan coal mining in this analysis. OSMRE designed a model mine for the Northwest region that reflects the Alaska's unique location, climate, topography, geology, and hydrology.

16. Technical Correction

TECHNICAL CORRECTION			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.1.1.3, pp. 4-35 to 4-36 "In June 2014, 785 active mines reported coal production to MSHA for 2013 (MSHA, 2014)… In fact, of the 785 actively-producing surface and underground mines operating in June, 2014, 640 were located in Appalachia." In Figure 4.1-5, the number of active coal mines adds up to 782.	The commenter is correct; the number of active coal mines in Figure 4.1-5 should add up to 785. The number of active coal mines in Appalachia was incorrectly labeled as 640, in Figure 4.1-5. This number has been updated to accurately reflect the number of active coal mines in this region (643). This edit bringing the total number of active coal mines shown in Figure 4.1-5 to 785, consistent with what was reported in the mentioned text.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.1.3, p. 4-66, Table 4.2.1-6, "Petty et al., 2010" row "Lower Cheat River Basin in Northern West Virginia" The correct name of the location is Lower Cheat River Basin, northern West Virginia.	The commenter is correct; the text has been edited.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.2.3.3, p. 4-139, Table 4.2.3-2 There are discrepancies in the calculation of totals for Alternatives 2, 3, 5, and 8.	The discrepancies are due to rounding. A note has been added to this table stating that totals may not sum due to rounding.
OSM-2010-0021-0696	Murray Energy Corporation	The subsections in Section 4.3.2 are misnumbered, with 4.3.2.2 through 4.3.2.4 missing.	We have incorporated these formatting changes into the FEIS.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.5.2.5, pp. 4-341 to 4-345, Table 4.5-1 There is an asterisk after "Status" at the top of the second column, but there is no explanation at the bottom of the table to explain what the asterisk means. Also, there is no explanation provided for what "F "and "P" mean in the Status column of the table.	The commenter is correct, the asterisk was intended to refer the reader to definitions of "F" and "P", however those were missing. Definitions have been added.
OSM-2010-0021-0696	Murray Energy Corporation	There are also contradictions between the RIA and DEIS. While the DEIS portrays increases in compliance-related jobs as a key factor in absorbing coal sector job losses, the RIA indicates that additional compliance and enforcement efforts associated with the Proposed Rule will constitute only a small burden for both industry and regulators. Exhibits 4-5 and 4-6 on pages 4-9 and 4-10 of the RIA show that compliance and enforcement activity as a result of the application of the Proposed Rule would impose an additional total of 1,014 hours of work per permit on industry and only 106.5 hours of work per permit on government. A full time, 52-week position, working a 40 hour week results in 2,080 annual hours of work. Using this approach, the combined employment opportunity	The analyses are based on the same evaluation. OSMRE did not intend to imply that compliance-related jobs could absorb the lost coal mining jobs. EIS section 4.3.1.2 has been clarified in response to public comments. Please refer to Master Response on Employment Effects and Multipliers for more details on this analysis.

TECHNICAL CORRECTION			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		associated with the compliance and enforcement component of the Proposed Rule is effectively a single halftime job per permit, per mine.	
OSM-2010-0018-10385	Wyoming County Commissioners Association	No coal mine located within the Wyoming-specific area encompassed in the Northern Rocky Mountains and Great Plains produced less than 4.3 million tons of coal in 2013. The average amount of coal produced in the PRB from all mines in 2013 was 31.18 million tons. Despite this easily verifiable data on coal production, the model mine for this region assumes annual production of only 2 million tons. This dramatic discrepancy between the "representative mine" and a realistic PRB mine calls into question every assumption made in the economic analysis as it relates to the regulatory impact on coal mining in Wyoming.	The commenter is mistaken about the size of the NRM model mine. It has an annual production of 27.2 million tons.
OSM-2010-0021-0696	Murray Energy Corporation	Section 1.0.3 Background, p. 1-5, second paragraph Thus, the 2008 SBZ rule took effect only in states with federal regulatory programs (of which only Tennessee and Washington have active coal mining or reasonably foreseeable coal mining) and on Indian lands. This statement is incorrect. Washington State likely does not have a foreseeable future in coal mining. As OSMRE recognizes later in the DEIS (at 3-2): "Coal production is not predicted in the reasonably foreseeable future in the other coal resource areas within the Northwest region (Oregon, Washington, and northern Alaska)."	The statement in Chapter 1 is true as mining has historically occurred in Washington. While the statement only clarifies the states in which the 2008 Stream Buffer Zone rule took effect, OSMRE agrees that the text could be confusing with regards to the discussion later in the EIS. The text has been removed from Chapter 1.
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.10.2.6, p. 3-331 "(Tennessee Department of Environmental Conservation (DEC), 2013)" The correct name of the agency is Tennessee Department of Environment and Conservation.	Edits made.
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.12.2, p. 3-364 "The eastern portion of Kentucky is considered to be part of the Appalachian Basin, while the western portion of Kentucky is considered to be part of the Illinois Basin (and the far western portion is in the Gulf region but no coal is mined in that part of the state). For purposes of this report, transportation statistics have been generated by county. Statistics for Kentucky counties located within the Appalachian Basin are presented in this section, and statistics for Kentucky counties located within the Illinois Basin are presented below." OSMRE should clarify which Kentucky counties are in each	The following Kentucky counties: Daviess, Henderson, McLean, Muhlenberg, Ohio and Webster counties were included in the Illinois Basin region. All others were included in the Appalachian Basin.

TECHNICAL CORRECTION			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		mining basin.	
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.12.4, p. 3-368 "Table 3.12-7 Texas, Other, percent of coal transported by mode by state of origin = 294" This is an error; the percent cannot exceed 100.	Edits made.
OSM-2010-0021-0696	Murray Energy Corporation	Section 3.14.2, p. 3-410"The unemployment rate across coal-producing countries was slightly below the national rate in 2011 (7.9percent compared with 8.1 percent nationwide)."The sentence contains a typo. The word "countries" should be changed to "counties."	Edits made.

17. Regulatory Flexibility Analysis

REGULATORY FLEXIBILITY ANALYSIS			
COMMENT ID	**AGENCY/NAME**	**COMMENT**	**RESPONSE**
OSM-2010-0021-0070	Luminant Mining Company LLC	Further, the DEIS fails to consider that impacts will be disproportionately felt by smaller mining companies, which comprise approximately 94 percent of all coal companies.	The Final Regulatory Flexibility Analysis (FRFA), presented in the RIA, describes not only the impacts of the rule on small entities as defined by SBA thresholds, but also provides additional detail describing potential impacts of the rule on operators with less than 20 employees. As shown, there were 188 mines, of which 167 are thought to be small entities, that reported production in 2015 and who recorded less than 20 employees. Impacts of the rule on these entities are anticipated to range from zero to 3.1 percent of estimated annual revenues. The FRFA has been revised to incorporate your concerns regarding the specific burdens faced by small operators.
OSM-2010-0021-0696	Murray Energy Corporation	Section 4.1.3, p. 4-39, sixth bullet As the DEIS states, Appalachia has hundreds of small companies (see DEIS, at 4-35, and p. 4-36 Table 4.1-2), so this amount would unduly burden these small companies, forcing them either to go out of business or sell to larger companies, which would in turn become even larger. It creates an unfair price advantage to levy the same requirements and costs across the board, when individual operations can vary significantly. This would cause a substantial number of job losses for all companies, as well as job losses for supporting businesses (e.g., suppliers, local businesses, service industry, etc.).	The FRFA acknowledges that some costs are more readily scaled to small operators than others; that is, some administrative burdens or other requirements could result in a more disproportionate cost to small operators. The FRFA has been revised to incorporate your concerns regarding the specific burdens faced by small operators. OSMRE notes that Section 507(c) of SMCRA, 30 U.S.C. § 1257(c), establishes the small operator assistance program (SOAP). To the extent that funds are appropriated for that program, this provision of SMCRA authorizes OSMRE to provide small operators with training and financial assistance in preparing certain elements of permit applications. An operator is eligible to receive training and assistance if his or her probable total annual production at all locations will not exceed 300,000 tons.
OSM-2010-0018-10055	Pennsylvania Coal Alliance	Not only are there significant environmental differences between Anthracite and Bituminous coal mine operations. There are also market differences as well. Anthracite coal production is about 0.2 percent of U.S. coal production. Bituminous coal mining in the United States totals nearly one billion tons annually, while Anthracite production is less	OSMRE agrees that the anthracite industry is a small component of annual coal production in the U.S., representing approximately 0.2 percent of U.S. total production in 2015. The industry is discussed fairly extensively in Chapter 3 of the FEIS. Due to its small size, a

REGULATORY FLEXIBILITY ANALYSIS			
COMMENT ID	AGENCY/NAME	COMMENT	RESPONSE
		than two million tons annually. Additionally, Anthracite coal mining markets are significantly different from bituminous coal markets. Most bituminous coal mined in the U.S. is used for either electric power generation or coked into metallurgical coal. Anthracite on the other hand is not used for electric generation, rather its markets are generally found in the home space heating market, steel production and water filtration markets. In addition, because of their size and limited production capacity as well as foreign government's subsidies to some of the worlds larger anthracite coal producers, U.S. Anthracite coal producers face more of a challenge from foreign imports and competition than do bituminous coal mine operators. Further, along with being a small fraction with regard to production, employment in the region represents just a small fraction of U.S. coal mining jobs. Given the nature and differences between Anthracite and bituminous coal mine operations, it does not make sense to just lump our industry with the soft coal industry. We believe that a separate Anthracite specific Environmental Impact Study and Regulatory Impact Analysis should be conducted for the Anthracite Region.	separate model mine that was specific to the anthracite industry was not designed. This point has been clarified in the FEIS and Final RIA. In response to your comment, OSMRE has added some additional details regarding the anthracite industry into the Final RIA. In 2015, the total Anthracite production was 2,118,000 tons of which 196,000 tons was underground and 1,922,000 was surface mined. The underground mining was produced by 15 mines which is 13,000 tons per year per mine on average. The surface mining was produced by 52 mines which is 37,000 tons per year per mine on average. Anthracite coal mining (in Pennsylvania only) is regulated by SMCRA/25 PA Chapter 88 with essentially the same rules and regulations as the bituminous coal industry. The Final RIA did not define a model mine specific to address anthracite mines due to its small contribution of this industry to the current level of U.S. coal production, the small average size of the anthracite mines, and the very site specific/proprietary mining methods used in anthracite mining, which make doing a model mine analysis problematic. However, we recognize that the impacts of the SPR on these mines may result in somewhat different impacts to these operations than other mining operations in the Northern Appalachian region.

K.4 List of Commenters
